# Geometric side of a local relative trace formula 

P. Delorme*, P. Harinck, S. Souaifi

#### Abstract

Following a scheme suggested by B. Feigon, we investigate a local relative trace formula in the situation of a reductive $p$-adic group $G$ relative to a symmetric subgroup $H=\underline{H}(F)$ where $\underline{H}$ is split over the local field F of characteristic zero and $G=\underline{G}(F)$ is the restriction of scalars of $\underline{H} /$ E relative to a quadratic unramified extension E of F . We adapt techniques of the proof of the local trace formula by J. Arthur in order to get a geometric expansion of the integral over $H \times H$ of a truncated kernel associated to the regular representation of $G$.

## A Appendix. Spherical character of a supercuspidal representation as weighted orbital integral

## Introduction

In this article, we investigate a local relative trace formula in the situation of $p$-adic groups relative to a symmetric subgroup. This work is inspired by the recent results of B. Feigon (see $[\mathrm{F}]$ ), where she investigated what she called a local relative trace formula on $P G L(2)$ and a local Kuznetsov trace formula for $U(2)$.

Before we describe our setting and results, we would like to explain on the toy model of finite groups the framework of the formulas of B. Feigon. We even start with the more general framework of the relative trace formula initiated by H. Jacquet (cf. [J], see also [O] for an account of some applications of this relative trace formula).

Let $G$ be a finite group and let $H, H^{\prime}, \Gamma$ be subgroups of $G$. We endow any finite set with the counting measure. We denote by $r$ the right regular representation of $G$ on $L^{2}(\Gamma \backslash G)$ and we consider the $H$-fixed linear form $\xi$ on $L^{2}(\Gamma \backslash G)$ defined by

$$
\begin{equation*}
\xi=\sum_{h \in H \cap \Gamma \backslash H} \delta_{\Gamma h} \tag{0.1}
\end{equation*}
$$

where $\delta_{\Gamma h}$ is the Dirac measure of the coset $\Gamma h$, or in other words

$$
\xi(\psi)=\int_{H \cap \Gamma \backslash H} \psi(\Gamma h) d h, \quad \psi \in L^{2}(\Gamma \backslash G) .
$$

We define similarly $\xi^{\prime}$ relative to $H^{\prime}$.
We view $\xi, \xi^{\prime}$ as elements of $L^{2}(\Gamma \backslash G)$ and we form the coefficient $c_{\xi, \xi^{\prime}}(g)=\left(r(g) \xi, \xi^{\prime}\right)$. Integrating over functions on $G$, it defines a "distribution" $\Theta$ on $G$ which is right invariant by $H$ and left invariant by $H^{\prime}$. The relative trace formula in this context gives two expressions of $\Theta(f)$ for $f$ a function on $G$, the first one, called the geometric side, in terms of orbital integrals, and the second one, called the spectral side, in terms of irreducible representations of $G$.

First we deal with the geometric side. For this purpose we introduce suitable orbital integrals. For $\gamma \in \Gamma$, we set $[\gamma]:=\left(H^{\prime} \cap \Gamma\right) \gamma(H \cap \Gamma)$ and one introduces two subgroups of $H^{\prime} \times H$

$$
\left(H^{\prime} \times H\right)_{\gamma}=\left\{\left(h^{\prime}, h\right) \mid h^{\prime} \gamma h^{-1}=\gamma\right\},\left(H^{\prime} \cap \Gamma \times H \cap \Gamma\right)_{\gamma}=\left(H^{\prime} \times H\right)_{\gamma} \cap(\Gamma \times \Gamma) .
$$

Then, we define the orbital integral of a function $f$ on $G$ by

$$
I([\gamma], f)=\int_{\left(H^{\prime} \times H\right)_{\gamma} \backslash\left(H^{\prime} \times H\right)} f\left(h^{\prime} \gamma h^{-1}\right) d h^{\prime} d h .
$$

Let $f$ be a function on $G$. Since $r(g) \delta_{\Gamma h}=\delta_{\Gamma h g^{-1}}$, the definition of $\xi$ and $\xi^{\prime}$ gives

$$
\Theta(f)=\sum_{g \in G} f(g) \Theta(g)=\sum_{g \in G} f(g) \frac{1}{v o l(\Gamma \cap H)} \frac{1}{\operatorname{vol}\left(\Gamma \cap H^{\prime}\right)} \sum_{h \in H} \sum_{h^{\prime} \in H^{\prime}}\left(\delta_{\Gamma h g^{-1}}, \delta_{\Gamma h^{\prime}}\right) .
$$

Changing $g$ in $g^{-1} h$ and using the fact that $\left(\delta_{\Gamma g}, \delta_{\Gamma h^{\prime}}\right)$ is equal to 1 for $g \in \Gamma h^{\prime}$ and to zero otherwise, one gets

$$
\begin{equation*}
\Theta(f)=\frac{1}{\operatorname{vol}(\Gamma \cap H)} \frac{1}{\operatorname{vol}\left(\Gamma \cap H^{\prime}\right)} \sum_{h \in H} \sum_{h^{\prime} \in H^{\prime}} \sum_{\gamma \in \Gamma} f\left(h^{\prime} \gamma h\right) . \tag{0.2}
\end{equation*}
$$

A simple computation of volumes leads to the geometric expression of $\Theta$ in terms of orbital integrals

$$
\begin{equation*}
\Theta(f)=\sum_{[\gamma] \in H^{\prime} \cap \Gamma \backslash \Gamma / \Gamma \cap H} \operatorname{vol}\left(\left(H^{\prime} \cap \Gamma \times H \cap \Gamma\right)_{\gamma} \backslash\left(H^{\prime} \times H\right)_{\gamma}\right) I([\gamma], f) . \tag{0.3}
\end{equation*}
$$

Let us shift into the spectral side. We decompose $L^{2}(\Gamma \backslash G)$ into isotypic components $\oplus_{\pi \epsilon \hat{G}} \mathcal{H}_{\pi}$. The restriction of $\xi$ and $\xi^{\prime}$ to $\mathcal{H}_{\pi}$ will be denoted $\xi_{\pi}$ and $\xi_{\pi}^{\prime}$ respectively. The spectral formula for $\Theta$ is the simple equality

$$
\begin{equation*}
\Theta=\sum_{\pi \in \hat{G}} c_{\xi_{\pi}, \xi_{\pi}^{\prime}} \tag{0.4}
\end{equation*}
$$

Notice that it might be also interesting to decompose further the representation into irreducible representations and the restriction of $\xi$ to each of them will be called a period.

There is a third interpretation of the distribution $\Theta$. If $f$ is a function on $G$, then the operator $r(f)$ on $L^{2}(\Gamma \backslash G)$ is an integral operator whose kernel $K_{f}$ is the function on $\Gamma \backslash G \times \Gamma \backslash G$ given by

$$
K_{f}(x, y)=\sum_{\gamma \in \Gamma} f\left(x^{-1} \gamma y\right) .
$$

By (0.2), one gets easily the following expression of $\Theta(f)$

$$
\begin{equation*}
\Theta(f)=\int_{\left(H^{\prime} \cap \Gamma \backslash H^{\prime}\right) \times(H \cap \Gamma \backslash H)} K_{f}\left(h^{\prime}, h\right) d h^{\prime} d h . \tag{0.5}
\end{equation*}
$$

This point of view is probably the best one. But it is important to have the representation theoretic meaning of $\Theta$.

The toy model for the local relative trace formula of B. Feigon appears as a particular case of the above relative trace formula. In that case, the groups $G, H$ and $H^{\prime}$ are products $G_{1} \times G_{1}, H_{1} \times H_{1}$ and $H_{1}^{\prime} \times H_{1}^{\prime}$ respectively and $\Gamma$ is the diagonal of $G_{1} \times G_{1}$. Then $\Gamma \backslash G$ identifies with $G_{1}$ and the right representation corresponds
to the representation $R$ of $G_{1} \times G_{1}$ on $L^{2}\left(G_{1}\right)$ given by $[R(x, y) \phi](g)=\phi\left(x^{-1} g y\right)$. Hence we have

$$
\xi(\psi)=\int_{H_{1}} \psi(h) d h, \quad \psi \in L^{2}\left(G_{1}\right)
$$

The spectral side is more concrete. If $\left(\pi_{1}, \mathcal{H}_{\pi_{1}}\right)$ is an irreducible unitary representation of $G_{1}$ then $G_{1} \times G_{1}$ acts on $\operatorname{End}\left(\mathcal{H}_{\pi_{1}}\right)$ by an irreducible representation denoted by $\pi$. It is unitary if we use the scalar product $(\cdot, \cdot)$ associated to the Hilbert-Schmidt norm. Moreover $L^{2}\left(G_{1}\right)$ is canonically isomorphic to the direct sum $\oplus_{\pi_{1} \in \widehat{G_{1}}} \operatorname{End}\left(\mathcal{H}_{\pi_{1}}\right)$. Let $P_{\pi}$ be the orthogonal projector onto the space of invariant vectors under $H_{1}$, where $\widehat{G_{1}}$ is the unitary dual of $G_{1}$. Then the period map $\xi_{\pi}$, which is a linear form on $\operatorname{End}\left(\mathcal{H}_{\pi_{1}}\right)$, is given by

$$
\xi_{\pi}(T)=\int_{H_{1}} \operatorname{Tr}\left(\pi_{1}(h) T\right) d h=\left(T, P_{\pi}\right), \quad T \in \operatorname{End}\left(\mathcal{H}_{\pi_{1}}\right)
$$

One further decomposes $\xi_{\pi}$ by using an orthonormal basis $\left(\eta_{\pi_{1}, i}\right)$ of the space of $H_{1}$-invariant vectors. We will use the identification of $\operatorname{End}\left(\mathcal{H}_{\pi_{1}}\right)$ with the tensor product of $\mathcal{H}_{\pi_{1}}$ with its conjugate complex vector space. Under this identification, one has

$$
P_{\pi}=\sum_{i} \eta_{\pi_{1}, i} \otimes \eta_{\pi_{1}, i}
$$

We define similar notations for $\xi^{\prime}$ relative to $H^{\prime}$. Then, for two functions $f_{1}, f_{2}$ on $G_{1}$, the spectral side (0.4) can be written

$$
\Theta\left(f_{1} \otimes f_{2}\right)=\sum_{\pi_{1} \in \hat{G}_{1}} \sum_{i, i^{\prime}} c_{\eta_{\pi_{1}, i}, \eta_{\pi_{1}, i^{\prime}}^{\prime}}\left(f_{1}\right) c_{\eta_{\pi_{1}, i, \eta_{\pi_{1}, i^{\prime}}^{\prime}}}\left(f_{2}\right)
$$

For the geometric side, we define the orbital integral of a function $f$ on $G_{1}$ by

$$
I(g, f)=\int_{\left(H_{1}^{\prime} \times H_{1}\right)_{g} \backslash H_{1}^{\prime} \times H_{1}} f\left(h^{\prime} g h^{-1}\right) d h d h^{\prime}
$$

which depends only on the double coset $H_{1}^{\prime} g H_{1}$. Then one gets by (0.3) the equality

$$
\Theta\left(f_{1} \otimes f_{2}\right)=\sum_{g \in H_{1}^{\prime} \backslash G_{1} / H_{1}} v(g) I\left(g, f_{1}\right) I\left(g, f_{2}\right)
$$

where the $v(g)$ 's are positive constants depending on volumes. Hence the final form of the local relative trace formula is:

$$
\sum_{g \in H_{1}^{\prime} \backslash G_{1} / H_{1}} v(g) I\left(g, f_{1}\right) I\left(g, f_{2}\right)=\sum_{\pi_{1} \in \hat{G}_{1}} \sum_{i, i^{\prime}} c_{\eta_{\pi_{1}, i}, \eta_{\pi_{1}, i^{\prime}}^{\prime}}\left(f_{1}\right) c_{\eta_{\pi_{1}, i}, \eta_{\pi_{1}, i^{\prime}}^{\prime}}\left(f_{2}\right)
$$

This formula allows us to invert the orbital integrals $I\left(g, f_{1}\right)$ for any $g \in$ $H_{1}^{\prime} \backslash G_{1} / H_{1}$. For this purpose, one chooses $g_{1} \in G_{1}$ and takes for $f_{2}$ the Dirac measure at $g_{1}$. Then $I\left(g_{1}, f_{2}\right)=1$ and the other orbital integrals of $f_{2}$ are zero. Hence

$$
v\left(g_{1}\right) I\left(g_{1}, f_{1}\right)=\sum_{\pi_{1} \in \hat{G}_{1}} \sum_{i, i^{\prime}} c_{\eta_{\pi_{1}, i}, \eta_{\pi_{1}, i^{\prime}}^{\prime}}\left(f_{1}\right) c_{\eta_{\pi_{1}, i}, \eta_{\pi_{1}, i^{\prime}}^{\prime}}\left(f_{2}\right) .
$$

In order to make the formula more precise, one needs to compute the constants $c_{\eta_{\pi_{1}, i, \eta_{\pi_{1}, i^{\prime}}^{\prime}}^{\prime}}\left(f_{2}\right)$.

The inversion of orbital integrals is one of our motivations to investigate a local relative trace formula in the situation of $p$-adic groups relative to a symmetric subgroup $H$ and we will take $H=H^{\prime}$.

In this article, we consider a reductive algebraic group $\underline{H}$ defined over a non archimedean local field F of characteristic 0 . We fix a quadratic unramified extension E of F and we consider the group $\underline{G}:=\operatorname{Res}_{\mathrm{E} / \mathrm{F}} \underline{H}$ obtained by restriction of scalars of $\underline{H}$. Here $\underline{H}$ is considered as a group defined over E. We denote by $H$ and $G$ the group of F-points of $\underline{H}$ and $\underline{G}$ respectively. Then $G$ is isomorphic to $\underline{H}(E)$ and $H$ appears as the fixed points of $G$ under the involution of $G$ induced by the nontrivial element of the Galois group of E/F. We assume that $\underline{H}$ is split over F and we fix a maximal split torus $A_{0}$ of $H$. The groups $G$ and $H$ correspond to $G_{1}$ and $H_{1}=H_{1}^{\prime}$ respectively in our example of a local relative trace formula for finite groups.

The starting point of our study is the analogue to the expression (0.5). We consider the regular representation $R$ of $G \times G$ on $L^{2}(G)$ given by $\left(R\left(g_{1}, g_{2}\right) \psi\right)(x)=$ $\psi\left(g_{1}^{-1} x g_{2}\right)$. Then for $f=f_{1} \otimes f_{2}$ where $f_{1}$ and $f_{2}$ are two smooth compactly supported functions on $G$, the corresponding operator $R(f)$ is an integral operator on $L^{2}(G)$ with smooth kernel

$$
K_{f}(x, y)=\int_{G} f_{1}(x g) f_{2}(g y) d g=\int_{G} f_{1}(g) f_{2}\left(x^{-1} g y\right) d g
$$

As $H$ may not be compact, even modulo the split component $A_{H}$ of the center of $H$, we shall truncate this kernel to integrate it. We multiply this kernel by a product of functions $u(x, T) u(y, T)$ where $u(\cdot, T)$ is the characteristic function of a large compact subset in $A_{H} \backslash H$ depending on a parameter $T \in a_{0}=\operatorname{Rat}\left(A_{0}\right) \otimes_{\mathbb{Z}} \mathbb{R}$ $\left(\operatorname{Rat}\left(A_{0}\right)\right.$ is the group of F-rational characters of $\left.A_{0}\right)$ as in [Ar3] (cf. (2.7)). As $H$ is split, we have $A_{H}=A_{G}$. Hence the kernel $K_{f}$ is left invariant by the diagonal $\operatorname{diag}\left(A_{H}\right)$ of $A_{H}$ and we can integrate the truncated kernel over $\operatorname{diag}\left(A_{H}\right) \backslash H \times H$. We set

$$
K^{T}(f):=\int_{\operatorname{diag}\left(A_{H}\right) \backslash(H \times H)} K_{f}\left(x_{1}, x_{2}\right) u\left(x_{1}, T\right) u\left(x_{2}, T\right) d \overline{\left(x_{1}, x_{2}\right)} .
$$

In [Ar3], J. Arthur studies the integral of $K_{f}(x, x) u(x, T)$ over $A_{G} \backslash G$ to obtain its local trace formula on reductive groups.

We study the geometric expression of the distribution $K^{T}(f)$ and its dependence on the parameter $T$. Our main results (Theorem 2.3 and Corollary 2.11) assert that $K^{T}(f)$ is asymptotic as $T$ approaches infinity to another distribution $J^{T}(f)$ of the form

$$
\begin{equation*}
J^{T}(f)=\sum_{k=0}^{N} p_{\xi_{k}}(T, f) e^{\xi_{k}(T)} \tag{0.6}
\end{equation*}
$$

where $\xi_{0}=0, \ldots \xi_{N}$ are distinct points of the dual space $i a_{0}^{*}$ and each $p_{\xi_{k}}(T, f)$ is a polynomial function in $T$. Moreover, the constant term $\tilde{J}(f):=p_{0}(0, f)$ of $J^{T}(f)$ is well-defined and uniquely determined by $K^{T}(f)$. We give an explicit expression of this constant term in terms of weighted orbital integrals.

These results are analogous to those of [Ar3] for the group case. Our proof follows closely the study by J. Arthur of the geometric side of his local trace formula which we were able to adapt under our assumptions to the case of double truncations.

In the first section, we introduce notation on groups and on symmetric spaces according to $[R R]$. The starting point of our study is the Weyl integration formula established in loc.cit., which takes into account the $(H, H)$-double classes of $\sigma$ regular elements of $G$ (cf. (1.30) and (1.32)). These double classes are expressed in terms of $\sigma$-tori, that are tori whose elements are anti-invariant by $\sigma$. Under our assumptions, there is a bijective correspondence $S \rightarrow S_{\sigma}$ between maximal tori of $H$ and maximal $\sigma$-tori of $G$ which preserves $H$-conjugacy classes.

Then the Weyl integration formula can be written in terms of Levi subgroups $M \in \mathcal{L}\left(A_{0}\right)$ of $H$ containing $A_{0}$ and $M$-conjugacy classes of maximal anisotropic tori of $M$ (cf. (1.33)):

$$
\int_{G} f(g) d g=\sum_{M \in \mathcal{L}\left(A_{0}\right)} c_{M} \sum_{S \in \mathcal{T}_{M}} \sum_{x_{m} \in \kappa_{S}} c_{S, x_{m}} \int_{S_{\sigma}}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 2} \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} f\left(h^{-1} x_{m} \gamma l\right)
$$

where $\kappa_{S}$ is a finite subset of $G, c_{M}$ and $c_{S, x_{m}}$ are positive constants, $\mathcal{T}_{M}$ is a suitable set of anisotropic tori of $M$ and $\Delta_{\sigma}$ is a jacobian.

A fundamental result for our proofs concerns the orbital integral $\mathcal{M}(f)$ of a compactly supported smooth function $f$ on $G$. It is defined on $\sigma$-regular points by

$$
\mathcal{M}(f)\left(x_{m} \gamma\right)=\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 4} \int_{\operatorname{diag}\left(A_{S}\right) \backslash H \times H} f\left(h^{-1} x_{m} \gamma l\right) d \overline{(h, l)},
$$

where $S$ is a maximal torus of $H, x_{m} \in \kappa_{S}$ and $\gamma \in S_{\sigma}$ such that $x_{m} \gamma$ is $\sigma$-regular. As in the group case using the exponential map and the property that each root of $S_{\sigma}$ has multiciplity 2 in the Lie algebra of $G$, we prove that the orbital integral is bounded on the subset of $\sigma$-regular points of $G$ (cf. Theorem 1.2).

In the second section, we explain the truncation process based on the notion of ( $H, M$ )-orthogonal sets and prove our main results. Using the Weyl integration formula, we can write

$$
K^{T}(f)=\sum_{M \in \mathcal{L}\left(A_{0}\right)} c_{M} \sum_{S \in \mathcal{T}_{M}} \sum_{x_{m} \in \kappa_{S}} c_{S, x_{m}} \int_{S_{\sigma}} K^{T}\left(x_{m}, \gamma, f\right) d \gamma
$$

where

$$
K^{T}\left(x_{m}, \gamma, f\right)=\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 2} \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} f_{1}\left(y_{1}^{-1} x_{m} \gamma y_{2}\right)
$$

$$
\times f_{2}\left(x_{1}^{-1} x_{m} \gamma x_{2}\right) u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) d \overline{\left(x_{1}, x_{2}\right)} d \overline{\left(y_{1}, y_{2}\right)}
$$

and

$$
u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)=\int_{A_{H} \backslash A_{M}} u\left(y_{1}^{-1} a x_{1}, T\right) u\left(y_{2}^{-1} a x_{2}, T\right) d a
$$

The function $J^{T}(f)$ is obtained in a similar way to $K^{T}(f)$ where we replace the weight function $u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ by another weight function $v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$.

The weight function $v_{M}$ is given by

$$
v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right):=\int_{A_{H} \backslash A_{M}} \sigma_{M}\left(h_{M}(a), \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right) d a
$$

where $\sigma_{M}(\cdot, \mathcal{Y})$ is the function defined in [Ar3, equation (3.8)] depending on a $(H, M)$-orthogonal set $\mathcal{Y}$ and $\mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ is a $(H, M)$-orthogonal set obtained as the "minimum" of two $(H, M)$-orthogonal sets $\mathcal{Y}_{M}\left(x_{1}, y_{1}, T\right)$ and $\mathcal{Y}_{M}\left(x_{2}, y_{2}, T\right)$ (cf. (2.4), Lemma 2.2 and (2.11)). If $\mathcal{Y}_{1}$ and $\mathcal{Y}_{2}$ are two $(H, M)$ orthogonal positive sets then the "minimum" $\mathcal{Z}$ of $\mathcal{Y}_{1}$ and $\mathcal{Y}_{2}$ satisfies the property that the convex hull $\mathcal{S}_{M}(\mathcal{Z})$ in $a_{H} \backslash a_{M}$ of the points of $\mathcal{Z}$ is the intersection of the convex hulls $\mathcal{S}_{M}\left(\mathcal{Y}_{1}\right)$ and $\mathcal{S}_{M}\left(\mathcal{Y}_{2}\right)$ in $a_{H} \backslash a_{M}$ of the points of $\mathcal{Y}_{1}$ and $\mathcal{Y}_{2}$ respectively.

If $\|T\|$ is large compared to $\left\|x_{i}\right\|,\left\|y_{i}\right\|, i=1,2$, then $\sigma_{M}\left(\cdot, \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right)$ is just the characteristic function of $\mathcal{S}_{M}\left(\mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right)$. In that case, this function is equal to the product of $\sigma_{M}\left(\cdot, \mathcal{Y}_{M}\left(x_{1}, y_{1}, T\right)\right)$ and $\sigma_{M}\left(\cdot, \mathcal{Y}_{M}\left(x_{2}, y_{2}, T\right)\right)$.

A key step of our proof is a good estimate of $\mid u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ $v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) \mid$ when $x_{i}, y_{i}, i=1,2$, satisfy $f_{1}\left(y_{1}^{-1} x_{m} \gamma y_{2}\right) f_{1}\left(x_{1}^{-1} x_{m} \gamma x_{2}\right) \neq 0$ for some $\gamma \in S_{\sigma}$ and $x_{m} \in \kappa_{S}$. Then, using that orbital integrals are bounded, we deduce our result on $\left|K^{T}(f)-J^{T}(f)\right|$.

This work is a first step towards a local relative trace formula. For the spectral side, we have to prove that $K^{T}(f)$ is asymptotic to a distribution $k^{T}(f)$ which is of general form (0.6) and constructed from spectral data. We hope that we can express the constant term of $k^{T}(f)$ in terms of regularized local period integrals introduced by B. Feigon in [F] in the same way as Jacquet-Lapid-Rogawski regularized period integrals for automorphic forms in [JLR]. We plan to explicate such a local relative trace formula for $P G L(2)$.
Acknowledgments. We thank warmly Bertrand Lemaire for his answers to our many questions on algebraic groups. We thank Bertrand Rémy and David Renard for helpful discussions. We thank also Guy Henniart for providing us a proof of (1.5).

## 1 Preliminaries

### 1.1 Reductive $p$-adic groups

Let F be a non archimedean local field of characteristic 0 and odd residual characteristic $q$. Let $|\cdot|_{F}$ denote the normalized valuation on F .

For any algebraic variety $\underline{M}$ defined over F , we identify $\underline{M}$ with $\underline{M}(\overline{\mathrm{~F}})$, where $\overline{\mathrm{F}}$ is an algebraic closure of F , and we set $M:=\underline{M}(\mathrm{~F})$.

We will use the same convention as in [W2]. One considers various algebraic groups $\underline{J}$ defined over F. Sentences as
"let $M$ be an algebraic group" will mean "let $M$ be the F-points of an algebraic group $\underline{M}$ defined over F "
and "let $A$ be a split torus" will mean "let $A$ be the group of F-points
of a torus, $\underline{A}$, defined and split over F ".
If $J$ is an algebraic group, one denotes by $\operatorname{Rat}(J)$ the group of its rational characters defined over F . If $V$ is a vector space, $V^{*}$ denotes its dual. If $V$ is real, $V_{\mathbb{C}}$ refers to its complexification.

Let $\underline{G}$ be an algebraic reductive group defined over F. We fix a maximal split torus $A_{0}$ of $G$ and we denote by $M_{0}$ its centralizer in $G$.

Let $A_{G}$ be the maximal split torus of the center of $G$ and let

$$
a_{G}:=\operatorname{Hom}_{\mathbb{Z}}(\operatorname{Rat}(G), \mathbb{R})
$$

One has the canonical map $h_{G}: G \rightarrow a_{G}$ which is defined by

$$
\begin{equation*}
e^{\left\langle h_{G}(x), \chi\right\rangle}=|\chi(x)|_{\mathrm{F}}, \quad x \in G, \chi \in \operatorname{Rat}(G) \tag{1.2}
\end{equation*}
$$

The restriction of rational characters from $G$ to $A_{G}$ induces an isomorphism

$$
\begin{equation*}
\operatorname{Rat}(G) \otimes_{\mathbb{Z}} \mathbb{R} \simeq \operatorname{Rat}\left(A_{G}\right) \otimes_{\mathbb{Z}} \mathbb{R} \tag{1.3}
\end{equation*}
$$

Notice that $\operatorname{Rat}\left(A_{G}\right)$ appears as a generating lattice in the dual space $a_{G}^{*}$ of $a_{G}$ and

$$
\begin{equation*}
a_{G}^{*} \simeq \operatorname{Rat}(G) \otimes_{\mathbb{Z}} \mathbb{R} \tag{1.4}
\end{equation*}
$$

The kernel $G^{1}$ of $h_{G}$ is the intersection over all characters $\chi \in \operatorname{Rat}(G)$ of $G$ of the kernels of $|\chi|_{F}$. The group $G^{1}$ is distinguished in $G$ and contains the derived group $G_{d e r}$ of $G$. Moreover, it is well-known that
the group $G^{1}$ is generated by the compact subgroups of $G$.
G. Henniart has communicated to us an unpublished proof of this result by N. Abe, F. Herzig, G. Henniart and M.F. Vigneras.

One denotes by $a_{G, F}$ (resp. $\tilde{a}_{G, F}$ ) the image of $G$ (resp., $A_{G}$ ) by $h_{G}$.
Then $G / G^{1}$ is isomorphic to the lattice $a_{G, F}$.
If $P$ is a parabolic subgroup of $G$ with Levi subgroup $M$, we keep the same notation with $M$ instead of $G$.

The inclusions $A_{G} \subset A_{M} \subset M \subset G$ determine a surjective morphism $a_{M, F} \rightarrow$ $a_{G, \mathrm{~F}}$ (resp. an injective morphism, $\tilde{a}_{G, \mathrm{~F}} \rightarrow \tilde{a}_{M, \mathrm{~F}}$ ) which extends uniquely to a surjective linear map $h_{M G}$ from $a_{M}$ to $a_{G}$ (resp. injective linear map between $a_{G}$ and $\left.a_{M}\right)$. The second map allows us to identify $a_{G}$ with a subspace of $a_{M}$ and the kernel of the first one, $a_{M}^{G}$, satisfies

$$
\begin{equation*}
a_{M}=a_{M}^{G} \oplus a_{G} . \tag{1.7}
\end{equation*}
$$

For $M=M_{0}$, we set $a_{0}:=a_{M_{0}}$ and $a_{0}^{G}:=a_{M_{0}}^{G}$. We fix a scalar product $(\cdot, \cdot)$ on $a_{0}$ which is invariant under the Weyl group $W\left(G, A_{0}\right)$ of $\left(G, A_{0}\right)$. Then $a_{G}$ identifies with the fixed point set of $a_{0}$ by $W\left(G, A_{0}\right)$ and $a_{0}^{G}$ is an invariant subspace of $a_{0}$ under $W\left(G, A_{0}\right)$. Hence it is the orthogonal subspace to $a_{G}$ in $a_{0}$. The space $a_{G}^{*}$ might be viewed as a subspace of $a_{0}^{*}$ by (1.7). Moreover, by definition of the surjective map $a_{0} \rightarrow a_{G}$, one deduces that
if $m_{0} \in M_{0}$ then $h_{G}\left(m_{0}\right)$ is the orthogonal projection of $h_{M_{0}}\left(m_{0}\right)$ onto $a_{G}$.
From (1.7) applied to $\left(M, M_{0}\right)$ instead of $(G, M)$, one obtains a decomposition $a_{0}=$ $a_{0}^{M} \oplus a_{M}$. From the $W\left(G, A_{0}\right)$-invariance of the scalar product on $a_{0}$, one gets:

The decomposition $a_{0}=a_{0}^{M} \oplus a_{M}$ is an orthogonal decomposition. The space $a_{M}^{*}$ appears as a subspace of $a_{0}^{*}$ and, in the identification of $a_{0}$ with $a_{0}^{*}$ given by the scalar product, $a_{M}^{*}$ identifies with $a_{M}$.

The decomposition $a_{M}=a_{M}^{G} \oplus a_{G}$ is orthogonal with respect to the restriction to $a_{M}$ of the $W\left(G, A_{0}\right)$-invariant scalar product on $a_{0}$, and the natural map $h_{M G}$ is identified with the orthogonal projection of $a_{M}$ onto $a_{G}$.

In particular, $a_{G, F}$ is the orthogonal projection of $a_{M, F}$ onto $a_{G}$. Moreover, we have $\tilde{a}_{G, \mathrm{~F}}=a_{G} \cap \tilde{a}_{M, \mathrm{~F}}$ (cf. [Ar3, equation (1.4)]).

By a Levi subgroup of $G$, we mean a group $M$ containing $M_{0}$ which is the Levi component of a parabolic subgroup of $G$. If $P$ is a parabolic subgroup containing $M_{0}$ then it has a unique Levi subgroup denoted by $M_{P}$ which contains $M_{0}$. We will denote by $N_{P}$ the unipotent radical of $P$.

For a Levi subgroup $M$, we write $\mathcal{L}(M)$ for the finite set of Levi subgroups of $G$ which contain $M$ and we also let $\mathcal{P}(M)$ denote the finite set of parabolic subgroups $P$ with $M_{P}=M$.

Let $K$ be the fixator of a special point in the apartment of $A_{0}$ in the Bruhat-Tits building. We have the Cartan decomposition

$$
\begin{equation*}
G=K M_{0} K \tag{1.11}
\end{equation*}
$$

If $P=M_{P} N_{P}$ is a parabolic subgroup of $G$ containing $M_{0}$, then

$$
\begin{equation*}
G=P K=M_{P} N_{P} K \tag{1.12}
\end{equation*}
$$

If $x \in G$, we can write

$$
\begin{equation*}
x=m_{P}(x) n_{P}(x) k_{P}(x), \quad m_{P}(x) \in M_{P}, n_{P}(x) \in N_{P}, k_{P}(x) \in K . \tag{1.13}
\end{equation*}
$$

We set

$$
\begin{equation*}
h_{P}(x):=h_{M_{P}}\left(m_{P}(x)\right) . \tag{1.14}
\end{equation*}
$$

The point $m_{P}(x)$ is defined up to multiplication by an element of $K \cap M_{P}$ but $h_{P}(x)$ does not depend of this choice.

We introduce a norm $\|\cdot\|$ on $G$ as in [W2, Section I.1] (called height function in loc.cit.). Let $\Lambda_{0}: G \rightarrow G L_{n}(\mathrm{~F})$ be an algebraic embedding. For $g \in G$, we write

$$
\Lambda_{0}(g)=\left(a_{i, j}\right)_{i, j=1 \ldots n}, \quad \Lambda_{0}\left(g^{-1}\right)=\left(b_{i, j}\right)_{i, j=1 \ldots n}
$$

We set

$$
\begin{equation*}
\|g\|:=\sup _{i, j} \sup \left(\left|a_{i, j}\right|_{\mathrm{F}},\left|b_{i, j}\right|_{\mathrm{F}}\right) . \tag{1.15}
\end{equation*}
$$

If $\Lambda: G \rightarrow G L_{d}(\mathrm{~F})$ is another algebraic embedding then the norm $\|\cdot\|_{\Lambda}$ attached to $\Lambda$ as above is equivalent to $\|\cdot\|$ in the following sense: there are a positive constant $C_{\Lambda}$ and a positive integer $d_{\Lambda}$ such that

$$
\|g\|_{\Lambda} \leqslant C_{\Lambda}\|g\|^{d_{\Lambda}}
$$

This allows us to use results of [W2] for estimates on norms.
The following properties of the norm $\|\cdot\|$ are immediate consequences of its definition:

$$
\begin{align*}
& 1 \leqslant\|x\|=\left\|x^{-1}\right\|, \quad x \in G,  \tag{1.16}\\
& \|x y\| \leqslant\|x\|\|y\|, \quad x, y \in G . \tag{1.17}
\end{align*}
$$

In order to have estimates, we introduce the following notation. Let $r$ be a positive integer. Let $f$ and $g$ be two positive functions defined on a subset $W$ of $G^{r}$

We write $f(x) \leqslant g(x), x \in W$, if and only if there are a positive constant $c$ and a positive integer $d$ such that $f(x) \leqslant c g(x)^{d}$ for all $x \in W$.

We write $f(x) \approx g(x), x \in W$, if $f(x) \leqslant g(x), x \in W$ and $g(x) \leqslant f(x)$, $x \in W$.

If $f_{1}, f_{2}$ and $f_{3}$ are positive functions on $G^{r}$, we clearly have:
if $f_{1}(x) \leqslant f_{2}(x), x \in W$ and $f_{2}(x) \leqslant f_{3}(x), x \in W$ then $f_{1}(x) \leqslant f_{3}(x), x \in W$,
if $f_{1}(x) \approx f_{2}(x), x \in W$ and $f_{2}(x) \approx f_{3}(x), x \in W$ then $f_{1}(x) \approx f_{3}(x), x \in W$.

Moreover, if $f_{1}, f_{2}, g_{1}$ and $g_{2}$ are positive functions on $G^{r}$ which take values greater or equal to 1 , we obtain easily the following properties:

1. for all positive integer $d$, we have $f_{1}(x) \approx f_{1}(x)^{d}, x \in W$,
2. if $f_{1}(x) \leqslant g_{1}(x), x \in W$ and $f_{2}(x) \leqslant g_{2}(x), x \in W$ then

$$
\begin{equation*}
\left(f_{1} f_{2}\right)(x) \leqslant\left(g_{1} g_{2}\right)(x), x \in W \tag{1.20}
\end{equation*}
$$

3. if $f_{1}(x) \approx g_{1}(x), x \in W$ and $f_{2}(x) \approx g_{2}(x), x \in W$ then $\left(f_{1} f_{2}\right)(x) \approx\left(g_{1} g_{2}\right)(x), x \in W$.

Since $\|x\|=\left\|x y y^{-1}\right\| \leqslant\|x y\|\|y\|$ and $\|x y\| \leqslant\|x\|\|y\|$, we obtain
If $\Omega$ is a compact subset of $G$, then $\|x\| \approx\|x \omega\|, \quad x \in G, \omega \in \Omega$.
Let $P=M_{P} N_{P}$ be a parabolic subgroup of $G$ containing $M_{0}$. Then each $x \in G$ can be written $x=m_{P}(x) n_{P}(x) k$ where $m_{P}(x) \in M_{P}, n_{P}(x) \in N_{P}$ and $k \in K$. By [W2, Lemma II.3.1], we then have

$$
\begin{equation*}
\left\|m_{P}(x)\right\|+\left\|n_{P}(x)\right\| \leqslant\|x\|, \quad x \in G . \tag{1.22}
\end{equation*}
$$

Recall that $G^{1}$ is the kernel of $h_{G}: G \rightarrow a_{G}$. Let us prove that

$$
\begin{equation*}
\|x a\| \approx\|x\|\|a\|, \quad x \in G^{1}, a \in A_{G} . \tag{1.23}
\end{equation*}
$$

According to the Cartan decomposition (1.11), if $g \in G$, we denote by $m_{0}(g)$ an element of $M_{0}$ such that there exist $k, k^{\prime} \in K$ with $g=k m_{0}(g) k^{\prime}$. Notice that $\left\|h_{M_{0}}\left(m_{0}(g)\right)\right\|$ does not depend on our choice of $m_{0}(g)$. By (1.21), one has

$$
\begin{equation*}
\|g\| \approx\left\|m_{0}(g)\right\|, \quad g \in G \tag{1.24}
\end{equation*}
$$

and, by [W2, equation I.1(6)], we have

$$
\begin{equation*}
\left\|m_{0}\right\| \approx e^{\left\|h_{M_{0}}\left(m_{0}\right)\right\|}, \quad m_{0} \in M_{0} \tag{1.25}
\end{equation*}
$$

Let $x \in G^{1}$ and $a \in A_{G}$. Then $m_{0}(x) \in G^{1} \cap M_{0}$ and $m_{0}(x a)=m_{0}(x) a$. Thus, one has $h_{G}\left(m_{0}(x)\right)=0$. We deduce from (1.8) that $h_{M_{0}}\left(m_{0}(x)\right)$ belongs to $a_{0}^{G}$. Since $h_{M_{0}}\left(m_{0}(x) a\right)=h_{M_{0}}\left(m_{0}(x)\right)+h_{M_{0}}(a)$ and $h_{M_{0}}(a) \in a_{G}$, we obtain by orthogonality that

$$
\frac{1}{2}\left(\left\|h_{M_{0}}\left(m_{0}(x)\right)\right\|+\left\|h_{M_{0}}(a)\right\|\right) \leqslant\left\|h_{M_{0}}\left(m_{0}(x) a\right)\right\| \leqslant\left\|h_{M_{0}}\left(m_{0}(x)\right)\right\|+\left\|h_{M_{0}}(a)\right\|
$$

Hence (1.23) follows from (1.24) and (1.25).
We denote by $C_{c}^{\infty}(G)$ the space of smooth functions on $G$ with compact support. We normalize Haar measures according to [Ar3, Section 1]. Unless otherwise stated, the Haar measure on a compact group will be normalized to have total volume 1.

Let $M$ be a Levi subgroup of $G$. We fix a Haar measure on $a_{M}$ so that the volume of the quotient $a_{M} / \tilde{a}_{M, \mathrm{~F}}$ equals 1 .

Let $P=M N_{P} \in \mathcal{P}(M)$. We denote by $\delta_{P}$ the modular function of $P$ given by

$$
\delta_{P}(m n)=e^{2 \rho_{P}\left(h_{M}(m)\right)}, m \in M, n \in N_{P},
$$

where $2 \rho_{P}$ is the sum of roots, with multiplicity, of $\left(P, A_{M}\right)$. Let $\bar{P}=M N_{\bar{P}}$ be the the parabolic subgroup which is opposite to $P$. If $d n$ is a Haar measure on $N_{P}$ then the number

$$
\gamma(P)=\int_{N_{P}} e^{2 \rho_{\bar{P}}\left(h_{\bar{P}}(n)\right)} d n
$$

is finite. Moreover, the measure $\gamma(P)^{-1} d n$ is independent of the choice of $d n$ and thus defines a canonical Haar measure on $N_{P}$.
If $d m$ is a Haar measure on $M$ then there exists a unique Haar measure $d g$ on $G$, independent of the choice of the parabolic subgroup $P$, such that

$$
\int_{G} f(g) d g=\frac{1}{\gamma(P) \gamma(\bar{P})} \int_{N_{P}} \int_{M} \int_{N_{\bar{P}}} f(n m \bar{n}) \delta_{P}(m)^{-1} d \bar{n} d m d n
$$

for $f \in C_{c}^{\infty}(G)$. If so, we say that $d m$ and $d g$ are compatible. Compatibility has the obvious transitivity property with respect to Levi subgroups of $M$. Using the Iwasawa decomposition (1.12), these measures satisfy

$$
\int_{G} f(g) d g=\frac{1}{\gamma(P)} \int_{K} \int_{M} \int_{N_{P}} f(m n k) d n d m d k
$$

### 1.2 The symmetric space $H \backslash G$

Let E be an unramified quadratic extension of F . Then $\mathrm{E}=\mathrm{F}[\tau]$ where $\tau^{2}$ is not a square in F . We denote by $\sigma$ the nontrivial element of the Galois group $\mathcal{G}$ al( $\mathrm{E} / \mathrm{F}$ ) of $\mathrm{E} / \mathrm{F}$. The normalized valuation $|\cdot|_{\mathrm{E}}$ on E satisfies $|x|_{\mathrm{E}}=|x|_{\mathrm{F}}^{2}$ for $x \in \mathrm{~F}$.

If $\underline{J}$ is an algebraic group defined over F , then $J$ is as usual its group of points over F . Let $\underline{J} \times_{\mathrm{F}} \mathrm{E}$ be the group, defined over E, obtained from $\underline{J}$ by extension of scalars. We consider the group

$$
\underline{\tilde{J}}:=\operatorname{Res}_{\mathrm{E} / \mathrm{F}}(\underline{J} \times \mathrm{F})
$$

defined over F, obtained by restriction of scalars.
With our convention, one has $\tilde{J}=\underline{\tilde{J}}(\mathrm{~F})$ and $\tilde{J}$ is isomorphic to $\underline{J}(\mathrm{E})$.
Let $\underline{H}$ be a reductive group defined over F . In all this article, we assume that $\underline{H}$ is split over F and we set $\underline{G}:=\underline{\tilde{H}}$ and $G:=\tilde{H}$. We fix a maximal split torus $A_{0}$ of $H$. Then $A_{0}$ is also a maximal split torus of $G$. We also have $A_{H}=A_{G}$.

The nontrivial element $\sigma$ of $\mathcal{G} a l(\mathrm{E} / \mathrm{F})$ induces an involution of $\underline{G}$ defined over F and denoted by the same letter. This automorphism $\sigma$ extends to an Eautomorphism $\sigma_{\mathrm{E}}$ on $\underline{G} \times_{\mathrm{F}} \mathrm{E}$.

We consider the canonical map $\varphi$ defined over F from $\underline{G}$ to $\left(\underline{H} \times_{\mathrm{F}} \mathrm{E}\right) \times\left(\underline{H} \times_{\mathrm{F}} \mathrm{E}\right)$ by $\varphi(g)=(g, \sigma(g))$.

Then $\varphi$ extends uniquely to an isomorphism $\Psi$ defined over E from $\underline{G} \times_{\mathrm{F}} \mathrm{E}$ to $\left(\underline{H} \times_{\mathrm{F}} \mathrm{E}\right) \times\left(\underline{H} \times_{\mathrm{F}} \mathrm{E}\right)$ such that $\Psi(g)=(g, \sigma(g))$ for all $g \in \underline{G}$.
Moreover, if $\Psi(g)=\left(g_{1}, g_{2}\right)$ then $\Psi\left(\sigma_{\mathrm{E}}(g)\right)=\left(g_{2}, g_{1}\right)$.
Now we turn to the description of the geometric structure of the symmetric space $\mathcal{S}=H \backslash G$ according to $[R R$, Sections 2 and 3].

Let $\underline{\mathfrak{g}}$ be the Lie algebra of $\underline{G}$ and $\mathfrak{g}$ be the Lie algebra of its F-points. We will say that $\mathfrak{g}$ is the Lie algebra of $G$ and the Lie algebra $\mathfrak{h}$ of $H$ consists of the elements of $\mathfrak{g}$ invariant by $\sigma$. We denote by $\mathfrak{q}$ the space of anti-invariant elements of $\mathfrak{g}$ by $\sigma$. Thus one has $\mathfrak{g}=\mathfrak{h} \oplus \mathfrak{q}$ and $\mathfrak{g}$ may be identified with $\mathfrak{h} \otimes_{F}$ E.

As in $[R R$, Section 2], we say that a subspace $\mathfrak{c}$ of $\mathfrak{q}$ is a Cartan subspace of $\mathfrak{q}$ if $\mathfrak{c}$ is a maximal abelian subspace of $\mathfrak{q}$ (or equivalently a maximal abelian subalgebra of $\mathfrak{q}$ ) made of semisimple elements. As $\mathrm{E}=\mathrm{F}[\tau]$, the multiplication by $\tau$ induces an isomorphism between the set of Cartan subspaces of $\mathfrak{q}$ and the set of Cartan subalgebras of $\mathfrak{h}$ which preserves $H$-conjugacy classes.

We denote by $\underline{\mathcal{P}}$ the connected component of 1 in the set of $x$ in $\underline{G}$ such that $\sigma(x)=x^{-1}$. Then the map $\underline{p}$ from $\underline{G}$ to $\underline{\mathcal{P}}$ defined by $\underline{p}(x)=x^{-1} \sigma(x)$ induces an isomorphim of affine varieties $\underline{p}: \underline{H} \backslash \underline{G} \rightarrow \underline{\mathcal{P}}$.

A torus $\underline{A}$ of $\underline{G}$ is called a $\sigma$-torus if $\underline{A}$ is a torus defined over F contained in $\underline{\mathcal{P}}$. Notice that such a torus is called a $\sigma$-split torus in $[\mathrm{RR}]$. We would rather change the terminology as $\sigma$-tori are not necessarily split over F. Each $\sigma$-torus is the centralizer in $\underline{\mathcal{P}}$ of a Cartan subspace of $\mathfrak{q}$, or equivalently of a Cartan subalgebra of $\mathfrak{h}$.

Let $S$ be a maximal torus of $H$. We denote by $\underline{S}_{\sigma}$ the connected component of $\underline{\tilde{S}} \cap \underline{\mathcal{P}}$. Then $\underline{S}_{\sigma}$ is a $\sigma$-torus defined over F which identifies with the anti-diagonal $\left\{\left(s, s^{-1}\right) ; s \in \underline{S}\right\}$ of $\underline{S} \times \underline{S}$ by the isomorphism (1.26). Thus $\underline{S}_{\sigma}$ is a maximal $\sigma$ torus and each maximal $\sigma$-torus arises in this way. The $H$-conjugacy classes of maximal tori of $H$ are in a bijective correspondence with the $H$-conjugacy classes of maximal $\sigma$-tori of $G$ by the map $S \mapsto S_{\sigma}$. The roots of $\underline{S}\left(\operatorname{resp} . \underline{S}_{\sigma}\right)$ in $\underline{\mathfrak{h}}=\operatorname{Lie}(\underline{H})$ (resp. $\underline{\mathfrak{q}} \otimes_{\mathrm{F}} \overline{\mathrm{F}}$ ) are the restrictions of the roots of $\underline{\tilde{S}}$ in $\underline{\mathfrak{g}}=\operatorname{Lie}(\underline{G})$.

Therefore, each root of $\underline{S}$ (resp. $\underline{S}_{\sigma}$ ) in $\underline{\mathfrak{g}}$ has multiplicity two. If $\underline{\tilde{S}}$ splits over a finite extension $\mathrm{F}^{\prime}$ of F , we denote by $\Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)\left(\right.$ resp. $\left.\Phi\left(S^{\prime}, \mathfrak{h}^{\prime}\right)\right)$ the set of roots of $\underline{S}_{\sigma}\left(\mathrm{F}^{\prime}\right)$ in $\mathfrak{g} \otimes_{\mathrm{F}} \mathrm{F}^{\prime}\left(\right.$ resp. $\underline{S}\left(\mathrm{~F}^{\prime}\right)$ in $\left.\mathfrak{h} \otimes_{\mathrm{F}} \mathrm{F}^{\prime}\right)$.
Let $\underline{\tilde{\mathfrak{s}}}$ be the Lie algebra of $\underline{\tilde{S}}$. Then the differential of each root $\alpha$ of $\Phi\left(\tilde{S}^{\prime \prime}, \mathfrak{g}^{\prime}\right)$ defines a linear form on $\tilde{\mathfrak{s}} \otimes_{\mathrm{F}} \mathrm{F}^{\prime}$ denoted by the same letter.
Let $\mathcal{G} a l(\overline{\mathrm{~F}} / \mathrm{F})$ be the Galois group of $\overline{\mathrm{F}} / \mathrm{F}$. By [RR, Section 3], the set of $\left(H, S_{\sigma}\right)$ double cosets in $\underline{H S}_{\sigma} \cap G$ are parametrized by the finite set $I$ of cohomology classes
in $H^{1}\left(\mathcal{G} a l(\overline{\mathrm{~F}} / \mathrm{F}), \underline{H} \cap \underline{S}_{\sigma}\right)$ which split in both $\underline{H}$ and $\underline{S}_{\sigma}$. To each such class $m$, we attach an element $x_{m} \in G$ of the form $x_{m}=h_{m} a_{m}^{-1}$ with $h_{m} \in \underline{H}$ and $a_{m} \in \underline{S}_{\sigma}$ such that $m_{\gamma}=h_{m}^{-1} \gamma\left(h_{m}\right)=a_{m}^{-1} \gamma\left(a_{m}\right)$ for all $\gamma \in \mathcal{G a l}(\overline{\mathrm{F}} / \mathrm{F})$.
1.1 Lemma. Let $x \in G$ such that $x=h s$ with $h \in \underline{H}$ and $s \in \underline{\tilde{S}}$. Then $x S x^{-1}$ is a maximal torus of $H$ and there exists $h^{\prime} \in H$ such that $x^{\prime}=h^{\prime} x$ centralizes the split connected component $A_{S}$ of $S$.

Proof. By replacing $S$ by a $H$-conjugate if necessary, we may assume that $A:=A_{S}$ is contained in the fixed maximal split torus $A_{0}$ of $H$. Since $H$ is split, $A_{0}$ is also a maximal split torus of $G$.

As $x=h s \in G$, the torus $\underline{S}^{\prime}:=x \underline{S} x^{-1}$ is equal to $h \underline{S} h^{-1} \subset \underline{H}$. Thus $\underline{S}^{\prime}$ is defined over F and is contained in $\underline{H}$. Hence we get the first assertion.

Let $S^{\prime}:=\underline{S}^{\prime}(\mathrm{F})$ and let $A^{\prime}$ be the split connected component of $S^{\prime}$. There exists $h_{1} \in H$ such that $h_{1} A^{\prime} h_{1}^{-1} \subset A_{0}$. We set $x_{1}=h_{1} x$. Then we have $A_{1}:=x_{1} A x_{1}^{-1} \subset$ $A_{0}$.

Let $M=Z_{G}(A)$ and $M_{1}=Z_{G}\left(A_{1}\right)=x_{1} M x_{1}^{-1}$. Then $A_{0}$ and $x_{1} A_{0} x_{1}^{-1}$ are maximal split tori of $M_{1}$. Therefore, there exists $y_{1} \in M_{1}$ such that $y_{1} x_{1} A_{0} x_{1}^{-1} y_{1}^{-1}=$ $A_{0}$. As $H$ is split, the Weyl group of $A_{0}$ in $G$ coincides with the Weyl group of $A_{0}$ in $H$. Thus there exist $h_{2} \in N_{H}\left(A_{0}\right)$ and $v \in Z_{G}\left(A_{0}\right)$ such that $z:=y_{1} x_{1}=h_{2} v$.

For $a \in A \subset A_{0}$, one has $z a z^{-1}=h_{2} a h_{2}^{-1}=y_{1} x_{1} a x_{1}^{-1} y_{1}^{-1}=x_{1} a x_{1}^{-1}$ since $x_{1} a x_{1}^{-1} \in A_{1}$ and $y_{1} \in M_{1}$. One deduces that $x^{\prime}:=h_{2}^{-1} h_{1} x$ centralizes $A$.

This lemma allows us to state the following result.
For each maximal torus $S$ of $H$, we can fix a finite set of representatives $\kappa_{S}=\left\{x_{m}\right\}_{m \in I}$ of the $\left(H, S_{\sigma}\right)$-double cosets in $\underline{H S}_{\sigma} \cap G$ such that each element $x_{m}$ may be written $x_{m}=h_{m} a_{m}^{-1}$ where $h_{m} \in \underline{H}$ centralizes $A_{S}$ and $a_{m} \in \underline{S}_{\sigma}$. Hence $x_{m}$ centralizes $A_{S}$.

### 1.3 Weyl integration formula and orbital integrals

We first recall basic notions on the symmetric space according to [RR, Section 3]. An element $x$ in $\underline{G}$ is called $\sigma$-semisimple if the double coset $\underline{H} x \underline{H}$ is Zariski closed. This is equivalent to say that $p(x)$ is a semisimple point of $\underline{G}$. We say that a $\sigma$ semisimple element $x$ is $\sigma$-regular if this closed double coset $\underline{H} x \underline{H}$ is of maximal dimension. This is equivalent to say that the centralizer of $\underline{p}(x)$ in $\mathfrak{q}$ (resp. $\underline{\mathcal{P}}$ ) is a Cartan subspace of $\mathfrak{q}$ (resp. a maximal $\sigma$-torus of $\underline{G}$ ).

We denote by $G^{\sigma-r e g}$ the set of $\sigma$-regular elements of $G$.
For $g \in G$, we denote by $D_{G}(g)$ the coefficient of the least power of $t$ appearing nontrivially in $\operatorname{det}(t+1-\operatorname{Ad}(g))$. We define the $H$-bi-invariant function $\Delta_{\sigma}$ on $G$ by $\Delta_{\sigma}(x)=D_{G}(\underline{p}(x))$. Then, by [RR, Lemmas 3.2. and 3.3], the set of $g \in G$ such that $\Delta_{\sigma}(g) \neq 0$ coincides with $G^{\sigma-r e g}$.

Let $S$ be a maximal torus of $H$ with Lie algebra $\mathfrak{s}$. Then $\tilde{\mathfrak{s}}:=\mathfrak{s} \otimes_{\mathrm{F}} \mathrm{E}$ identifies with the Lie algebra of $\tilde{S}$. For $g \in x_{m} S_{\sigma}$ with $x_{m} \in \kappa_{S}$, one has

$$
\begin{equation*}
\Delta_{\sigma}(g)=D_{G}(\underline{p}(g))=\operatorname{det}(1-\operatorname{Ad}(\underline{p}(g)))_{\mathfrak{g} / \tilde{\mathfrak{s}}} . \tag{1.29}
\end{equation*}
$$

By loc.cit., Theorem 3.4(1), the set $G^{\sigma-r e g}$ is a disjoint union

$$
\begin{equation*}
G^{\sigma-r e g}=\bigcup_{\{S\}_{H}} \bigcup_{x_{m} \in \kappa_{S}} H\left(\left(x_{m} S_{\sigma}\right) \cap G^{\sigma-r e g}\right) H \tag{1.30}
\end{equation*}
$$

where $\{S\}_{H}$ runs the $H$-conjugacy classes of maximal tori of $H$.
If $x_{m} \in \kappa_{S}$ then $x_{m}=h_{m} a_{m}$ for some $h_{m} \in \underline{H}$ and $a_{m} \in \underline{S}_{\sigma}$, hence $\underline{p}\left(x_{m}\right)=a_{m}^{-2}$ commutes with $S$ and $S_{\sigma}$. Therefore for $\gamma \in S_{\sigma}$, we have

$$
\underline{p}\left(x_{m} \gamma\right)=\underline{p}\left(x_{m}\right) \gamma^{-2} \quad \text { and } \quad H x_{m} \gamma S=H x_{m} \gamma .
$$

We have the following Weyl integration formula (cf. loc.cit., Theorem 3.4(2)):

Let $f$ be a compactly supported smooth function on $G$, then we have

$$
\begin{equation*}
\int_{G} f(y) d y=\sum_{\{S\}_{H}} \sum_{x_{m} \in \kappa_{S}} c_{S, x_{m}}^{0} \int_{S_{\sigma}}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 2} \int_{S \backslash H} \int_{H} f\left(h x_{m} \gamma l\right) d h d \bar{l} d \gamma, \tag{1.31}
\end{equation*}
$$

where the constants $c_{S, x_{m}}^{0}$ are explicitly given in loc.cit., Theorem 3.4(1).
For our purpose, we need another version of this Weyl integration formula. Let $S$ be a maximal torus of $H$. We denote by $A_{S}$ its split connected component. Since the quotient $A_{S} \backslash S$ is compact, by our choice of measure, the integration over $S \backslash H$ in the Weyl formula above can be replaced by an integration over $A_{S} \backslash H$. Moreover, it is convenient to change $h$ into $h^{-1}$. As every $x_{m} \in \kappa_{S}$ commutes with $A_{S}$ (cf. (1.28)), one can replace the integration over $\left(A_{S} \backslash H\right) \times H$ by an integration over $\operatorname{diag}\left(A_{S}\right) \backslash(H \times H)$, where $\operatorname{diag}\left(A_{S}\right)$ is the diagonal of $A_{S}$. This gives the following Weyl integration formula equivalent to (1.31):

$$
\begin{equation*}
\int_{G} f(y) d y=\sum_{\{S\}_{H}} \sum_{x_{m} \in \kappa_{S}} c_{S, x_{m}}^{0} \int_{S_{\sigma}}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 2} \int_{\operatorname{diag}\left(A_{S}\right) \backslash(H \times H)} f\left(h^{-1} x_{m} \gamma l\right) \overline{d(h, l)} d \gamma . \tag{1.32}
\end{equation*}
$$

We will now describe the $H$-conjugacy classes of maximal tori of $H$ in terms of Levi subgroups $M$ in $\mathcal{L}\left(A_{0}\right)$ and $M$-conjugacy classes of some tori of $M$.

Let $M \in \mathcal{L}\left(A_{0}\right)$ and $N_{H}(M)$ be its normalizer in $H$. If $S$ is a maximal torus of $M$, we denote by $W(M, S)$ (resp. $W(H, S)$ ) its Weyl group in $M$ (resp. H). We choose a set $\mathcal{T}_{M}$ of representatives for the $M$-conjugacy classes of maximal tori $S$ in
$M$ such that $A_{M} \backslash S$ is compact. For $M, M^{\prime} \in \mathcal{L}\left(A_{0}\right)$, we write $M \sim M^{\prime}$ if $M$ and $M^{\prime}$ are conjugate under $H$.

Let $S$ be a maximal torus of $H$ whose split connected component $A_{S}$ is contained in $A_{0}$. Then the centralizer $M$ of $A_{S}$ belongs to $\mathcal{L}\left(A_{0}\right)$ and $S$ is a maximal torus of $M$ such that $A_{M} \backslash S$ is compact. If $S^{\prime}$ is a maximal torus $H$-conjugated to $S$ such that $A_{S^{\prime}}$ is contained in $A_{0}$, then the centralizer $M^{\prime}$ of $A_{S^{\prime}}$ in $H$ belongs to $\mathcal{L}\left(A_{0}\right)$ and $M^{\prime} \sim M$.

Since each maximal torus of $H$ is $H$-conjugated to a maximal torus $S$ such that $A_{S} \subset A_{0}$, we obtain a surjective map $S \mapsto\{S\}_{H}$ from the set of $S$ in $\mathcal{T}_{M}$, where $M$ runs through a system of representatives of $\mathcal{L}\left(A_{0}\right)_{/ \sim}$, to the set of $H$-conjugacy classes of maximal tori of $H$.

Let $M \in \mathcal{L}\left(A_{0}\right)$. By [Ko, equation (7.12.3)], the cardinal of the class of $M$ in $\mathcal{L}\left(A_{0}\right)_{\sim}^{\sim}$ is equal to

$$
\frac{\left|W\left(H, A_{0}\right)\right|}{\left|W\left(M, A_{0}\right)\right|\left|N_{H}(M) / M\right|},
$$

where $N_{H}(M)$ is the normalizer of $M$ in $H$.
According to loc.cit., Lemma 7.1, if $S$ is a maximal torus of $M$, then the number of $M$-conjugacy classes of maximal tori $S^{\prime}$ in $M$, such that $S^{\prime}$ is $H$-conjugated to $S$, is equal to

$$
\frac{\left|N_{H}(M) / M\right||W(M, S)|}{|W(H, S)|}
$$

Therefore, we can rewrite (1.32) as follows:

$$
\begin{align*}
\int_{G} f(g) d g=\sum_{M \in \mathcal{L}\left(A_{0}\right)} c_{M} & \sum_{S \in \mathcal{T}_{M}} \sum_{x_{m} \in \kappa_{S}} c_{S, x_{m}} \int_{S_{\sigma}}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 2}  \tag{1.33}\\
& \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} f\left(h^{-1} x_{m} \gamma l\right) \overline{d(h, l)} d \gamma
\end{align*}
$$

where

$$
c_{M}=\frac{\left|W\left(M, A_{0}\right)\right|}{\left|W\left(H, A_{0}\right)\right|} \quad \text { and } \quad c_{S, x_{m}}=\frac{|W(H, S)|}{|W(M, S)|} c_{S, x_{m}}^{0}
$$

Let $f \in C_{c}^{\infty}(G)$. We define the orbital integral $\mathcal{M}(f)$ of $f$ on $G^{\sigma-r e g}$ as follows. Let $S$ be a maximal torus of $H$. For $x_{m} \in \kappa_{S}$ and $\gamma \in S_{\sigma}$ such that $x_{m} \gamma \in G^{\sigma-r e g}$, we set

$$
\begin{align*}
\mathcal{M}(f)\left(x_{m} \gamma\right) & :=\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 4} \int_{\operatorname{diag}\left(A_{S}\right) \backslash(H \times H)} f\left(h^{-1} x_{m} \gamma l\right) d \overline{(h, l)}  \tag{1.34}\\
& =\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 4} \int_{S \backslash H} \int_{H} f\left(h x_{m} \gamma l\right) d h d \bar{l} .
\end{align*}
$$

Our definition corresponds, up to a positive constant factor, to [RR, Definition 3.8]. Indeed, by definition of $\Delta_{\sigma}$, we have $\Delta_{\sigma}\left(x_{m} \gamma\right)=D_{G}\left(\underline{p}\left(x_{m} \gamma\right)\right)$. Since we can write
$x_{m}=h_{m} a_{m}$ with $h_{m} \in \underline{H}$ and $a_{m} \in \underline{S}_{\sigma}$, we have $\underline{p}\left(x_{m} \gamma\right)=\underline{p}\left(x_{m}\right) \gamma^{-2}=a_{m}^{-2} \gamma^{-2}$ for $\gamma \in S_{\sigma}$. Let $\mathrm{F}^{\prime}$ be an extension of E such that $\overline{\tilde{S}}$ splits over $\mathrm{F}^{\prime}$ and $a_{m} \in \underline{S}_{\sigma}\left(\mathrm{F}^{\prime}\right)$. Since each root $\alpha$ of $\underline{S}_{\sigma}\left(\mathrm{F}^{\prime}\right)$ in $\mathfrak{g} \otimes \mathrm{F}^{\prime}$ have multiplicity $m(\alpha)=2$, using notation of (1.27), we obtain:

$$
\Delta_{\sigma}\left(x_{m} \gamma\right)=\prod_{\alpha \in \Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)}\left(1-\underline{p}\left(x_{m}\right)^{\alpha} \gamma^{-2 \alpha}\right)^{2}=\prod_{\alpha \in \Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)}\left(\gamma^{\alpha}-\underline{p}\left(x_{m}\right)^{\alpha} \gamma^{-\alpha}\right)^{2} .
$$

Hence

$$
\begin{aligned}
\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}^{\prime}}^{1 / 4} & =\prod_{\alpha \in \Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)}\left|\left(\gamma^{\alpha}-\underline{p}\left(x_{m}\right)^{\alpha} \gamma^{-\alpha}\right)^{m(\alpha)-1}\right|_{\mathrm{F}^{\prime}}^{1 / 2} \\
& =\prod_{\alpha \in \Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)}\left|\left(\gamma^{\alpha}-\underline{p}\left(x_{m}\right)^{\alpha} \gamma^{-\alpha}\right)\right|_{\mathrm{F}^{\prime}}^{1 / 2}
\end{aligned}
$$

Then the Weyl integration formula (1.31) is given in terms of orbital integrals as in [RR, p. 126] by

$$
\int_{G} f(y) d y=\sum_{\{S\}_{H}} \sum_{x_{m} \in \kappa_{S}} c_{S, x_{m}}^{0} \int_{S_{\sigma}}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 4} \mathcal{M}(f)\left(x_{m} \gamma\right) d \gamma
$$

1.2 Theorem. Let $f \in C_{c}^{\infty}(G)$ and $S$ be a maximal torus of $H$. Let $x_{m} \in \kappa_{S}$.

1. There exists a compact set $\Omega$ in $S_{\sigma}$ such that, for any $\gamma$ in the complementary of $\Omega$ with $x_{m} \gamma \in G^{\sigma-r e g}$, one has $\mathcal{M}(f)\left(x_{m} \gamma\right)=0$.
2. One has

$$
\sup _{\gamma \in S_{\sigma} ; x_{m} \gamma \in G^{\sigma-r e g}}\left|\mathcal{M}(f)\left(x_{m} \gamma\right)\right|<+\infty .
$$

Proof. The proof follows the one of the group case (see [HC3, proof of Theorem 14]). We write it here for convenience of the reader.
Let us first show 1. Let $\omega$ be the support of $f$. We consider the set $\omega_{S}$ of elements $\gamma$ in $S_{\sigma}$ such that $x_{m} \gamma$ is in the closure of $H \omega H$. For $g \in G$, we consider the polynomial function

$$
\begin{equation*}
\operatorname{det}(1-t-\operatorname{Ad} \underline{p}(g))=t^{n}+q_{n-1}(g) t^{n-1}+\ldots+q_{l}(g) t^{l} \tag{1.35}
\end{equation*}
$$

where $l$ is the rank of $G$ and $n$ is its dimension. Each $q_{j}$ is a $H \times H$ biinvariant regular function on $G$ and thus is bounded on $x_{m} \omega_{S}$. Therefore, the roots of $\operatorname{det}(1-$ $t-\operatorname{Ad} \underline{p}(g))$ are bounded on $x_{m} \omega_{S}$.

For $\bar{\gamma} \in S_{\sigma}$, we have $\underline{p}\left(x_{m} \gamma\right)=\underline{p}\left(x_{m}\right) \gamma^{-2}$. We choose a finite extension $\mathrm{F}^{\prime}$ of F such that $\underline{\tilde{S}}$ splits over $\mathrm{F}^{\prime}$ and $\underline{p}\left(x_{m}\right) \in \underline{S}_{\sigma}\left(\mathrm{F}^{\prime}\right)$. Using notation of (1.27), the roots of $\operatorname{det}\left(1-t-\operatorname{Ad} \underline{p}\left(x_{m} \gamma\right)\right)$ are the numbers $\left(1-\underline{p}\left(x_{m}\right)^{\alpha} \gamma^{-2 \alpha}\right)$ for $\alpha \in \Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)$. Since these roots are bounded on $x_{m} \omega_{S}$, we obtain that the maps $\gamma \rightarrow \gamma^{\alpha}, \alpha \in \Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)$, are bounded on $\omega_{S}$. This implies that $\omega_{S}$ is bounded, and hence the closure $\Omega$ of $\omega_{S}$ satisfies the first assertion.

It remains to show 2. According to 1., if $\gamma \notin \Omega$ then $\mathcal{M}(f)\left(x_{m} \gamma\right)=0$. Thus it is enough to prove that, for each $\gamma_{0} \in S_{\sigma}$, there exists a neighborhood $V_{\gamma_{0}}$ of $\gamma_{0}$ in $S_{\sigma}$ such that

$$
\begin{equation*}
\sup _{\gamma \in V_{\gamma_{0}, x_{m} \gamma \in G^{\sigma-r e g}}}\left|\mathcal{M}(f)\left(x_{m} \gamma\right)\right|<+\infty . \tag{1.36}
\end{equation*}
$$

Let $y_{0}:=\underline{p}\left(x_{m} \gamma_{0}\right)$. Let us first assume that $y_{0}$ is central in $G$. Then we have $\Delta_{\sigma}\left(x_{m} \gamma_{0} \gamma\right)=D_{G}\left(y_{0} \gamma^{-2}\right)=D_{G}\left(\gamma^{-2}\right)$ for $\gamma \in S_{\sigma}$ and $x_{m} \gamma_{0} h\left(x_{m} \gamma_{0}\right)^{-1} \in H$ for $h \in H$. We define the function $f_{0}$ on $G$ by $f_{0}(g):=f\left(x_{m} \gamma_{0} g\right)$. Then we have $\mathcal{M}\left(f_{0}\right)(\gamma)=$ $\mathcal{M}(f)\left(x_{m} \gamma_{0} \gamma\right)$ for $\gamma \in S_{\sigma} \cap G^{\sigma-r e g}$. Therefore we can restrict ourselves to the case $y_{0}=1$. As in the group case, we use the exponential map "exp", which is well defined in a neighborhood of 0 in $\mathfrak{g}$, since the characteristic of $F$ is equal to zero (cf. [HC4, Section 10]). As in [HC1, proof of Lemma 15], we can choose a H invariant open neighborhood $V_{0}$ of 0 in $\mathfrak{h}$ such that the map $X \in V_{0} \mapsto \exp (\tau X)$ is an isomorphism, and an homeomorphism onto its image, and such that there exists a $H$-invariant function $\varphi \in C_{c}^{\infty}(\mathfrak{h})$ such that $\varphi(X)=1$ for $X \in V_{0}$. We define $\bar{f}$ in $C_{c}^{\infty}(\mathfrak{h})$ by $\bar{f}(X)=\varphi(X) \int_{H} f(h \exp (\tau X)) d h$.

Let $\mathfrak{s}$ be the Lie algebra of $S$. For $X \in \mathfrak{s}$, we set $\eta(X)=\left|\operatorname{det}(\operatorname{ad} X)_{\mathfrak{h} / \mathfrak{s}}\right|_{\mathrm{F}}$. We consider a finite extension $\mathrm{F}^{\prime}$ of F such that $\underline{\tilde{S}}$ splits over $\mathrm{F}^{\prime}$ and $\underline{p}\left(x_{m}\right) \in \underline{S}_{\sigma}\left(\mathrm{F}^{\prime}\right)$. We use here notation introduced in (1.27). Since each root of $S_{\sigma}^{\prime}$ in $\mathfrak{g}^{\prime}$ has multiplicity 2 , we have for $X \in V_{0}$,

$$
\begin{gathered}
\frac{\left|\Delta_{\sigma}(\exp \tau X)\right|_{\mathrm{F}^{\prime}}^{1 / 2}}{\eta(X)}=\frac{\left|D_{G^{\prime}}(\exp (-2 \tau X))\right|_{\mathrm{F}^{\prime}}^{1 / 2}}{\eta(X)}=\frac{\prod_{\alpha \in \Phi\left(S^{\prime}, \mathfrak{h}^{\prime}\right)}\left|1-e^{2 \tau \alpha(X)}\right|_{\mathrm{F}^{\prime}}}{\prod_{\alpha \in \Phi\left(S^{\prime}, \mathfrak{h}^{\prime}\right)}|\alpha(X)|_{\mathrm{F}^{\prime}}} \\
\quad=|2 \tau|_{\mathrm{F}^{\prime}}^{\left|\Phi\left(S^{\prime}, \mathfrak{h}^{\prime}\right)\right|} \prod_{\alpha \in \Phi\left(S^{\prime}, \mathfrak{h}^{\prime}\right)}\left|1+\tau \alpha(X)+\frac{4 \tau^{2} \alpha(X)^{2}}{3!}+\ldots\right|_{\mathrm{F}^{\prime}}
\end{gathered}
$$

We can reduce $V_{0}$ in such way that each term of this product is equal to 1 . Thus we obtain

$$
\begin{aligned}
\mathcal{M}(f)(\exp \tau X) & =|2 \tau|_{\mathrm{F}^{\prime}}^{\left|\Phi\left(S^{\prime}, h^{\prime}\right)\right|} \eta(X)^{1 / 2} \int_{H / S}\left(\int_{H} f(h \exp \tau \operatorname{Ad}(l) X) d h\right) d \bar{l} \\
& =|2 \tau|_{\mathrm{F}^{\prime}}^{\left|\Phi\left(S^{\prime}, h^{\prime}\right)\right|} \eta(X)^{1 / 2} \int_{H / S} \bar{f}(\operatorname{Ad}(l) X) d \bar{l}
\end{aligned}
$$

for $X \in V_{0}$. Hence the estimate (1.36) follows from the result on the Lie algebra given in [HC3, Theorem 13].

Now, if $y_{0}=\underline{p}\left(x_{m} \gamma_{0}\right)$ is not central in $G$, we consider the centralizer $\underline{\mathcal{Z}}$ of $y_{0}$ in $\underline{H}$. Let $\underline{\mathcal{Z}}^{0}$ be the identity component of $\underline{\mathcal{Z}}$. By [Bo, Section III.9], the group $\underline{\mathcal{Z}}^{0}$ is defined over F. As usual, we set $\underline{\tilde{\mathcal{Z}}}^{0}:=\operatorname{Res}_{\mathrm{E} / \mathrm{F}}\left(\underline{\mathcal{Z}}^{0} \times \mathrm{F}\right.$ E) and we denote by $\underline{\tilde{\mathfrak{z}}}$ its Lie algebra. By definition of $\tilde{\mathfrak{z}}$, one has:

$$
\left|\operatorname{det}\left(1-\operatorname{Ad}\left(y_{0}\right)\right)_{\mathfrak{g} / \tilde{\mathfrak{z}}}\right|_{\mathrm{F}} \neq 0 .
$$

Thus there exists a neighborhood $V$ of 1 in $S_{\sigma}$ such that, for all $\gamma \in V$, then

$$
\begin{equation*}
\left|\operatorname{det}\left(1-\operatorname{Ad}\left(y_{0} \gamma^{-2}\right)\right)_{\mathfrak{g} / \mathfrak{z}}\right|_{\mathrm{F}}=\left|\operatorname{det}\left(1-\operatorname{Ad}\left(y_{0}\right)_{\mathfrak{g} / \mathfrak{z}}\right)\right|_{\mathrm{F}} \neq 0 . \tag{1.37}
\end{equation*}
$$

Let $\omega$ be the support of $f$. From [HC3, Lemma 19], there exist a neighborhood $V_{1}$ of $y_{0}$ in $\tilde{S}$ and a compact subset $\overline{C_{G}}$ of $\tilde{\mathcal{Z}}^{0} \backslash G$ such that, if $g \in G$ satsifies $g^{-1} V_{1} g \cap$ $\underline{p}(\omega) \neq \varnothing$, then its image $\bar{g}$ in $\tilde{Z}^{0} \backslash G$ belongs to $\overline{C_{G}}$.

We choose a neighborhood $W$ of 1 in $S_{\sigma}$ such that $W \subset V$ and $p\left(x_{m} \gamma_{0} \gamma\right)=$ $y_{0} \gamma^{-2} \in V_{1}$ for all $\gamma \in W$. By [Bo, Section III.9.1], the quotient $\mathcal{Z}^{0} \backslash \bar{H}$ is a closed subset of $\tilde{\mathcal{Z}}^{0} \backslash G$. Hence
the set $\bar{C}:=\overline{C_{G}} \cap \mathcal{Z}^{0} \backslash H$ is a compact subset of $\mathcal{Z}^{0} \backslash H$ such that, if $l \in H$ satisfies $l^{-1} y_{0} \gamma^{-2} l \in \underline{p}(\omega)$ for some $\gamma \in W$, then its image $\bar{l}$ in $\mathcal{Z}^{0} \backslash H$ belongs to $\bar{C}$.

Let $\gamma \in W$ such that $x_{m} \gamma_{0} \gamma \in G^{\sigma-r e g}$. One has:

$$
\begin{equation*}
\int_{S \backslash H} \int_{H} f\left(h x_{m} \gamma_{0} \gamma l\right) d h d \bar{l}=\int_{\mathcal{Z}^{0} \backslash H} \int_{S \backslash \mathcal{Z}^{0}} \int_{H} f\left(h x_{m} \gamma_{0} \gamma \xi l\right) d h d \bar{\xi} d \bar{l} . \tag{1.39}
\end{equation*}
$$

By our choice of $W$, the map

$$
\bar{l} \in \mathcal{Z}^{0} \backslash H \mapsto \int_{S \backslash \mathcal{Z}^{0}} \int_{H} f\left(h x_{m} \gamma_{0} \gamma \xi l\right) d h d \bar{\xi}
$$

vanishes outside $\bar{C}$. We choose $u \in C_{c}^{\infty}(H)$ such that the map $\bar{u} \in C_{c}^{\infty}\left(\mathcal{Z}^{0} \backslash H\right)$, defined by $\bar{u}(\bar{l}):=\int_{\mathcal{Z}^{0}} u(\xi l) d \xi$, is equal to 1 on $\bar{C}$. As $u$ and $f$ are compactly supported, the map

$$
\Phi: z \in \tilde{\mathcal{Z}}^{0} \mapsto \int_{H} u(l) \int_{H} f\left(h x_{m} \gamma_{0} z l\right) d h d l
$$

is well-defined.
Since $y_{0}=\underline{p}\left(x_{m} \gamma_{0}\right)=\left(x_{m} \gamma_{0}\right)^{-1} \sigma\left(x_{m} \gamma_{0}\right)$, we have $\xi\left(x_{m} \gamma_{0}\right)^{-1} \sigma\left(x_{m} \gamma_{0}\right)=$ $\left(x_{m} \gamma_{0}\right)^{-1} \sigma\left(x_{m} \gamma_{0}\right) \xi$ for $\xi \in \mathcal{Z}^{0}$. Thus $x_{m} \gamma_{0} \xi\left(x_{m} \gamma_{0}\right)^{-1} \in H$ and hence $\Phi$ is left invariant by $\mathcal{Z}^{0}$.

We claim that $\Phi \in C_{c}^{\infty}\left(\mathcal{Z}^{0} \backslash \tilde{\mathcal{Z}}^{0}\right)$. Indeed, fix $l$ in the support of $u$. If $f\left(h x_{m} \gamma_{0} z l\right)$ is nonzero for some $h \in H$ and $z \in \tilde{\mathcal{Z}}^{0}$, then $\underline{p}\left(h x_{m} \gamma_{0} z l\right)=p\left(x_{m} \gamma_{0} z l\right)$ belongs to $\underline{p}(\omega)$. Since $z$ commutes with $y_{0}=\underline{p}\left(x_{m} \gamma_{0}\right)$, we have $\underline{p}\left(x_{m} \gamma_{0} z l \overline{)}=l^{-1} y_{0} \underline{p}(z) \sigma(l)\right.$. As $\bar{u}$ is compactly supported, we get that $\Phi(z)=0$ when $\underline{p}(z)$ is outside a compact set. Hence the map $\Phi$ is a compactly supported function on $\mathcal{Z}^{0} \backslash \tilde{\mathcal{Z}}^{0}$.

By assumption, the function $f$ is right invariant by a compact open subgroup of $G$. Thus $f$ is right invariant by some compact open subgroup of $H$. We denote by $\tau_{l} f$ the right translate of $f$ by an element $l \in G$. Since $u$ is compactly supported, the vector space generated by $\tau_{l} f$, when $l \in H$ runs through the support of $u$, is finite dimensional. Hence one can find a compact open subgroup $J_{1}$ of $\tilde{Z}^{0}$ such that,
for each $l$ in the support of $u$, the function $\tau_{l} f$ is right invariant by $J_{1}$. This implies that $\Phi$ is smooth and our claim follows.

Therefore, there exists $\varphi \in C_{c}^{\infty}\left(\tilde{\mathcal{Z}}^{0}\right)$ such that:

$$
\Phi(z)=\int_{\mathcal{Z}^{0}} \varphi(\xi z) d \xi=\int_{H} u(l) \int_{H} f\left(h x_{m} \gamma_{0} z l\right) d h d l, \quad z \in \tilde{\mathcal{Z}}^{0}
$$

We obtain

$$
\begin{aligned}
\int_{S \backslash \mathcal{Z}^{0}} \int_{\mathcal{Z}^{0}} \varphi\left(\xi_{1} \gamma \xi_{2}\right) d \xi_{1} d \bar{\xi}_{2} & =\int_{H} u(l)\left(\int_{S \backslash \mathcal{Z}^{0}} \int_{H} f\left(h x_{m} \gamma_{0} \gamma \xi_{2} l\right) d h d \bar{\xi}_{2}\right) d l \\
& =\int_{\mathcal{Z}^{0} \backslash H} \int_{\mathcal{Z}^{0}} u\left(\xi_{1} l\right)\left(\int_{S \backslash \mathcal{Z}^{0}} \int_{H} f\left(h x_{m} \gamma_{0} \gamma \xi_{2} \xi_{1} l\right) d h d \bar{\xi}_{2}\right) d \xi_{1} d \bar{l} \\
& =\int_{\mathcal{Z}^{0} \backslash H} \bar{u}(\bar{l})\left(\int_{S \backslash \mathcal{Z}^{0}} \int_{H} f\left(h x_{m} \gamma_{0} \gamma \xi_{2} l\right) d h d \bar{\xi}_{2}\right) d \bar{l} .
\end{aligned}
$$

The map $\bar{u}$ being equal to 1 on the compact set $\bar{C}$, we obtain, using (1.3) and by definition of $\bar{C}$ (cf. (1.38)):

$$
\int_{S \backslash \mathcal{Z}^{0}} \int_{\mathcal{Z}^{0}} \varphi\left(\xi_{1} \gamma \xi_{2}\right) d \xi_{1} d \bar{\xi}_{2}=\int_{S \backslash H} \int_{H} f\left(h x_{m} \gamma_{0} \gamma l\right) d h d \bar{l}
$$

By (1.37) and the choice of $W$, one has

$$
\left|D_{G}\left(y_{0} \gamma^{-2}\right)\right|_{\mathrm{F}}=\left|D_{\tilde{\mathcal{Z}}^{0}}\left(\gamma^{-2}\right)\right|_{\mathrm{F}}\left|\operatorname{det}\left(1-\operatorname{Ad}\left(y_{0}\right)\right)_{\mathfrak{g} / \tilde{\mathfrak{z}}}\right|_{\mathrm{F}}, \quad \gamma \in W .
$$

Then we get, for $\gamma \in W$ satisfying $x_{m} \gamma_{0} \gamma \in G^{\sigma-r e g}$ :

$$
\mathcal{M}(f)\left(x_{m} \gamma_{0} \gamma\right)=\left|\operatorname{det}\left(1-\operatorname{Ad}\left(y_{0}\right)\right)_{\mathfrak{g} / \tilde{\mathfrak{z}}}\right|_{\mathrm{F}}^{1 / 4}\left|D_{\tilde{\mathcal{Z}}^{0}}\left(\gamma^{-2}\right)\right|_{\mathrm{F}}^{1 / 4} \int_{S \backslash \mathcal{Z}^{0}} \int_{\mathcal{Z}^{0}} \varphi\left(\xi_{1} \gamma \xi_{2}\right) d \xi_{1} d \bar{\xi}_{2}
$$

Since $\left|D_{\tilde{\mathcal{Z}}^{0}}\left(\gamma^{-2}\right)\right|_{\mathrm{F}}$ coincides with the function $\left|\Delta_{\sigma}\right|_{\mathrm{F}}$ for the group $\tilde{Z}^{0}$ evaluated at $\gamma$ (cf. (1.29)), the estimate (1.36) for $f$ is obtained by applying the first case to $\varphi$ defined on $\tilde{\mathcal{Z}}^{0}$.

## 2 Geometric side of the local relative trace formula

### 2.1 Truncation

In this section, we will recall some needed results of [Ar3, Section 3]. We keep notation of Section 1.1 for the group $H$. Since $H$ is split, one has $M_{0}=A_{0}$. We fix a Levi subgroup $M \in \mathcal{L}\left(A_{0}\right)$ of $H$. Let $P \in \mathcal{P}(M)$. We recall that $A_{M}$ denotes the maximal split connected component of $M$.

Let $\Sigma_{P}$ be the set of roots of $A_{M}$ in the Lie algebra of $P, \Sigma_{P}^{r}$ the subset of reduced roots and $\Delta_{P}$ the subset of simple roots.

As usual, for $\beta \in \Delta_{P}$, the "co-root" $\check{\beta} \in a_{M}$ is defined as follows: if $P \in \mathcal{P}\left(A_{0}\right)$ is a minimal parabolic subgroup, then $\check{\beta}=2(\beta, \beta)^{-1} \beta$, where $a_{0}^{*}$ identifies with $a_{0}$ through the scalar product on $a_{0}$. In the general case, we choose $P_{0} \in \mathcal{P}\left(A_{0}\right)$ contained in $P$. Then there exists a unique $\alpha \in \Delta_{P_{0}}$ such that $\beta=\alpha_{\mid a_{M}}$. The "co-root" $\check{\beta}$ is the projection of $\check{\alpha}$ onto $a_{M}$ with respect to the decomposition $a_{0}=$ $a_{M} \oplus a_{0}^{M}$. This projection does not depend of the choice of $P_{0}$.

We denote by $a_{P}^{+}$the positive Weyl chamber of elements $X \in a_{M}$ satisfying $\alpha(X)>0$ for all $\alpha \in \Sigma_{P}$.

Let $M \in \mathcal{L}\left(A_{0}\right)$. A set of points in $a_{M}$ indexed by $P \in \mathcal{P}(M)$

$$
\mathcal{Y}=\mathcal{Y}_{M}:=\left\{Y_{P} \in a_{M} ; P \in \mathcal{P}(M)\right\}
$$

is called a $(H, M)$-orthogonal set if, for any pair of adjacent parabolic subgroups $P, P^{\prime}$ in $\mathcal{P}(M)$ whose chambers in $a_{M}$ share the wall determined by the simple root $\alpha \in \Delta_{P} \cap\left(-\Delta_{P^{\prime}}\right)$, one has $Y_{P}-Y_{P}^{\prime}=r_{P, P^{\prime}} \check{\alpha}$ for some real number $r_{P, P^{\prime}}$. The orthogonal set is called positive if every number $r_{P, P^{\prime}}$ is nonnegative. For example, this is the case when the number

$$
\begin{equation*}
d(\mathcal{Y})=\inf _{\left\{\alpha \in \Delta_{P} ; P \in \mathcal{P}(M)\right\}} \alpha\left(Y_{P}\right) \tag{2.1}
\end{equation*}
$$

is nonnegative.
One example is the set

$$
\left\{-h_{P}(x) ; P \in \mathcal{P}(M)\right\}
$$

defined for any point $x \in H$. Indeed, this is a positive $(H, M)$-orthogonal set according to [Ar1, Lemma 3.6].

If $L$ belongs to $\mathcal{L}(M)$ and $Q$ is a group in $\mathcal{P}(L)$, we define $Y_{Q}$ to be the projection onto $a_{L}$ of any point $Y_{P}$, with $P \in \mathcal{P}(M)$ and $P \subset Q$. Then $Y_{Q}$ is independent of $P$ and $\mathcal{Y}_{L}:=\left\{Y_{Q} ; Q \in \mathcal{P}(L)\right\}$ is a $(H, L)$ orthogonal set.

We shall write $\mathcal{S}_{M}(\mathcal{Y})$ for the convex hull in $a_{M} / a_{H}$ of a $(H, M)$-orthogonal set $\mathcal{Y}$. Notice that $\mathcal{S}_{M}(\mathcal{Y})$ does only depend on the projection onto $a_{M}^{H}$ of each $Y_{P} \in \mathcal{Y}$, $P \in \mathcal{P}(M)$.

If each $Y_{P}$, for $P \in \mathcal{P}(M)$, is in the positive Weyl chamber $a_{P}^{+}$(this condition is equivalent to say that $d(\mathcal{Y})$ is positive), we have a simple description of $\mathcal{S}_{M}(\mathcal{Y}) \cap a_{P}^{+}$ (cf. [Ar3, Lemma 3.1]). We denote by $\left(\omega_{\gamma}^{P}\right)_{\gamma \in \Delta_{P}}$ the set of weights, that is the dual basis in $\left(a_{M}^{H}\right)^{*}$ of the set of co-roots $\left\{\check{\gamma} ; \gamma \in \Delta_{P}\right\}$. Then we have

$$
\begin{equation*}
\mathcal{S}_{M}(\mathcal{Y}) \cap a_{P}^{+}=\left\{X \in a_{P}^{+} ; \omega_{\gamma}^{P}\left(X-Y_{P}\right) \leqslant 0, \gamma \in \Delta_{P}\right\} . \tag{2.3}
\end{equation*}
$$

We now recall a decomposition of the characteristic function of $\mathcal{S}_{M}(\mathcal{Y})$ valid when $\mathcal{Y}$ is positive (cf. [Ar3, equation (3.8)]). Suppose that $\Lambda$ is a point in $a_{M, \mathbb{C}}^{*}$ whose real part $\Lambda_{R} \in a_{M}^{*}$ is in general position. For $P \in \mathcal{P}(M)$, let $\Delta_{P}^{\Lambda}$ be the set of simple roots $\alpha \in \Delta_{P}$ such that $\Lambda_{R}(\check{\alpha})<0$. Let $\varphi_{P}^{\Lambda}$ be the characteristic function of the set of $X \in a_{M}$ such that $\omega_{\alpha}^{P}(X)>0$ for each $\alpha \in \Delta_{P}^{\Lambda}$ and $\omega_{\alpha}^{P}(X) \leqslant 0$ for each $\alpha$ in the complementary of $\Delta_{P}^{\Lambda}$ in $\Delta_{P}$. We define

$$
\begin{equation*}
\sigma_{M}(X, \mathcal{Y}):=\sum_{P \in \mathcal{P}(M)}(-1)^{\left|\Delta_{P}^{\Lambda}\right|} \varphi_{P}^{\Lambda}\left(X-Y_{P}\right) \tag{2.4}
\end{equation*}
$$

Then:
By [Ar3, Section 3, p. 22], the function $\sigma_{M}(\cdot, \mathcal{Y})$ vanishes on the complementary of $\mathcal{S}_{M}(\mathcal{Y})$ and is bounded. Moreover, if $\mathcal{Y}$ is positive, then $\sigma_{M}(\cdot, \mathcal{Y})$ is exactly the characteristic function of $\mathcal{S}_{M}(\mathcal{Y})$.

For $P \in \mathcal{P}(M)$, we denote by $\left(\tilde{\omega}_{\gamma}^{P}\right)_{\gamma \in \Delta_{P}}$ the set of coweights, that is the dual basis in $a_{M}^{H}$ of $\Delta_{P}$.
2.1 Lemma. Let $P$ and $P^{\prime}$ be two adjacent parabolic subgroups in $\mathcal{P}(M)$ whose chambers in $a_{M}$ share the wall determined by the simple root $\alpha \in \Delta_{P} \cap\left(-\Delta_{P^{\prime}}\right)$. Then:

1. For all $\beta$ in $\Delta_{P}-\{\alpha\}$, there exists a unique $\beta^{\prime}$ in $\Delta_{P^{\prime}}-\{\alpha\}$ such that $\beta^{\prime}=$ $\beta+k_{\beta} \alpha$ where $k_{\beta}$ is a nonnegative integer. Moreover, the map $\beta \mapsto \beta^{\prime}$ is a bijection between $\Delta_{P}-\{\alpha\}$ and $\Delta_{P^{\prime}}-\{-\alpha\}$.
2. For all $\beta$ in $\Delta_{P}-\{\alpha\}$, one has $\tilde{\omega}_{\beta^{\prime}}^{P^{\prime}}=\tilde{\omega}_{\beta}^{P}$.

Proof. We denote by $\mathbb{N}$ the set of nonnegative integers and by $\mathbb{N}^{*}$ the subset of positive integers.

We will first show 1. As $P$ and $P^{\prime}$ are adjacent, we have $\Sigma_{P^{\prime}}=\left(\Sigma_{P}-\{\alpha\}\right) \cup\{-\alpha\}$. Let $\beta \in \Delta_{P}-\{\alpha\}$. If $\beta \in \Delta_{P^{\prime}}$, then we set $\beta^{\prime}:=\beta$. Assume that $\beta$ is not in $\Delta_{P^{\prime}}$. Since $\beta \in \Sigma_{P^{\prime}}$, there exists $\Theta \subset \Delta_{P^{\prime}}-\{-\alpha\}$ such that $\beta=\sum_{\delta \in \Theta} n_{\delta} \delta-k_{\beta} \alpha$, where the $n_{\delta}$ 's are positive integers and $k_{\beta}$ is a nonnegative integer. Each $\delta$ in $\Theta$ belongs to $\Sigma_{P}$. Therefore, there are nonnegative integers $\left(r_{\delta, \eta}\right)_{\eta \in \Delta_{P}}$ such that $\delta=\sum_{\eta \in \Delta_{P}} r_{\delta, \eta} \eta$. Set $\beta_{1}:=\sum_{\delta \in \Theta} n_{\delta} \delta=\beta+k_{\beta} \alpha$. Let $\gamma \in \Delta_{P}-\{\alpha\}$. If $\gamma \neq \beta$, one has $\beta_{1}\left(\tilde{\omega}_{\gamma}^{P}\right)=\beta\left(\tilde{\omega}_{\gamma}^{P}\right)=0$. Thus, for each $\delta \in \Theta$, we have $r_{\delta, \gamma}=0$. Hence $\delta=r_{\delta, \beta} \beta+r_{\delta, \alpha} \alpha$.

On the other hand, one has $\beta_{1}\left(\tilde{\omega}_{\beta}^{P}\right)=\beta\left(\tilde{\omega}_{\beta}^{P}\right)=1$. Thus, for all $\delta \in \Theta$, one has $\sum_{\delta \in \Theta} n_{\delta} r_{\delta, \beta}=1$. Since $n_{\delta} \in \mathbb{N}^{*}$ and $r_{\delta, \beta} \in \mathbb{N}$, one deduces that there exists a unique $\delta_{0} \in \Theta$ such that $r_{\delta_{0}, \beta} \neq 0$ and one has $n_{\delta_{0}}=r_{\delta_{0}, \beta}=1$. This implies that $\Theta=\left\{\delta_{0}\right\}$ and $\beta=\delta_{0}-k_{\beta} \alpha$. We can take $\beta^{\prime}:=\delta_{0}$. Hence we obtain the existence of $\beta^{\prime}$ in all cases.

If $\beta_{1}^{\prime} \in \Delta_{P^{\prime}}$ satisfies $\beta_{1}^{\prime}=\beta+k_{\beta}^{1} \alpha$, then $\beta^{\prime}=\beta_{1}^{\prime}+\left(k_{\beta}-k_{\beta}^{1}\right) \alpha$. Since the roots $\beta_{1}^{\prime}, \beta^{\prime}$ and $-\alpha$ belong to the set $\Delta_{P^{\prime}}$ of simple roots, we deduce that $\beta_{1}^{\prime}=\beta^{\prime}$. This gives the unicity of $\beta^{\prime}$.

Let $\gamma$ and $\beta$ be in $\Delta_{P}$ such that $\gamma^{\prime}=\beta^{\prime}$. Then we have $\beta=\gamma+\left(k_{\gamma}-k_{\beta}\right) \alpha$. Since $\gamma, \beta$ and $\alpha$ belong to $\Delta_{P}$, the same argument as above leads to $\beta=\gamma$. Hence, the map $\beta \mapsto \beta^{\prime}$ is injective.

It now remains to show 2. Let $\beta \in \Delta_{P}-\{\alpha\}$. By definition, we have $\beta^{\prime}=\beta+k_{\beta} \alpha \in$ $\Delta_{P^{\prime}}-\{-\alpha\}$ with $k_{\beta} \in \mathbb{N}$. Thus $\alpha\left(\tilde{\omega}_{\beta^{\prime}}^{P^{\prime}}\right)=\alpha\left(\tilde{\omega}_{\beta}^{P}\right)=0$ and $\beta\left(\tilde{\omega}_{\beta^{\prime}}^{P^{\prime}}\right)=\beta^{\prime}\left(\tilde{\omega}_{\beta^{\prime}}^{P^{\prime}}\right)=1$. If $\gamma \in \Delta_{P}-\{\beta, \alpha\}$, then $\gamma^{\prime}=\gamma+k_{\gamma} \alpha$ is different from $\beta^{\prime}$ by assertion 1 . Thus we have $\gamma\left(\tilde{\omega}_{\beta^{\prime}}^{P^{\prime}}\right)=\gamma^{\prime}\left(\tilde{\omega}_{\beta^{\prime}}^{P^{\prime}}\right)=0$. One deduces that $\tilde{\omega}_{\beta^{\prime}}^{P^{\prime}}=\tilde{\omega}_{\beta}^{P}$.

The above Lemma allows us to define the minimum between two orthogonal sets.
For $Y^{1}$ and $Y^{2}$ in $a_{M}$, we denote by $\inf ^{P}\left\{Y^{1}, Y^{2}\right\}$ the unique element $Z$ in $a_{M}^{H}$ such that, for all $\gamma \in \Delta_{P}$, one has $\left(\tilde{\omega}_{\gamma}^{P}, Z\right)=$ $\inf \left\{\left(\tilde{\omega}_{\gamma}^{P}, Y^{1}\right),\left(\tilde{\omega}_{\gamma}^{P}, Y^{2}\right)\right\}$.
2.2 Lemma. Let $\mathcal{Y}^{1}=\left\{Y_{P}^{1}, P \in \mathcal{P}(M)\right\}$ and $\mathcal{Y}^{2}=\left\{Y_{P}^{2}, P \in \mathcal{P}(M)\right\}$ be two $(H, M)$ orthogonal sets. Let $\mathcal{Z}:=\inf \left(\mathcal{Y}^{1}, \mathcal{Y}^{2}\right)$ be the set of $Z_{P}:=\inf ^{P}\left\{Y_{P}^{1}, Y_{P}^{2},\right\}$ when $P$ runs $\mathcal{P}(M)$.

1. The set $\mathcal{Z}$ is a $(H, M)$-orthogonal set.
2. If $d\left(\mathcal{Y}^{j}\right)>0$ for $j=1,2$, then $d(\mathcal{Z})>0$. In this case, the convex hull $\mathcal{S}_{M}(\mathcal{Z})$ is the intersection of $\mathcal{S}_{M}\left(\mathcal{Y}^{1}\right)$ and $\mathcal{S}_{M}\left(\mathcal{Y}^{2}\right)$.

Proof. Let $P$ and $P^{\prime}$ be two adjacent parabolic subgroups in $\mathcal{P}(M)$ whose chambers in $a_{M}$ share the wall determined by the simple root $\alpha \in \Delta_{P} \cap\left(-\Delta_{P^{\prime}}\right)$. Let $\gamma \in \Delta_{P}-$ $\{\alpha\}$. By definition of orthogonal sets, one has, for $j=1$ or 2 , $\left(\tilde{\omega}_{\gamma}^{P}, Y_{P}^{j}\right)=\left(\tilde{\omega}_{\gamma}^{P}, Y_{P^{\prime}}^{j}\right)$. By Lemma 2.1, we have $\tilde{\omega}_{\gamma}^{P}=\tilde{\omega}_{\gamma^{\prime}}^{P^{\prime}}$. Hence we obtain $\left(\tilde{\omega}_{\gamma}^{P}, Z_{P}\right)=\left(\tilde{\omega}_{\gamma^{\prime}}^{P^{\prime}}, Z_{P^{\prime}}\right)$ and $\left(\tilde{\omega}_{\gamma^{\prime}}^{P^{\prime}}, Z_{P^{\prime}}\right)=\left(\tilde{\omega}_{\gamma}^{P}, Z_{P^{\prime}}\right)$. Since the scalar product on $a_{0}$ identifies $a_{M}$ to $a_{M}^{*}$, one deduces that $Z_{P}-Z_{P^{\prime}}$ is proportional to $\check{\alpha}$. The assertion 1. then follows.

Let us show 2. Let $j \in\{1,2\}$ and $P \in \mathcal{P}(M)$. By definition, we have $d\left(\mathcal{Y}^{j}\right)>0$ if and only if $\alpha\left(Y_{P}^{j}\right)>0$ for all $\alpha \in \Delta_{P}$. By [Ar1, Corollary 2.2], this implies that $\left(\tilde{\omega}_{\alpha}^{P}, Y_{P}^{j}\right)>0$ for all $\alpha \in \Delta_{P}$. Let $\alpha \in \Delta_{P}$. Writing

$$
Y_{P}^{j}=\left(\tilde{\omega}_{\alpha}^{P}, Y_{P}^{j}\right) \alpha+\sum_{\beta \in \Delta_{P}-\{\alpha\}}\left(\tilde{\omega}_{\beta}^{P}, Y_{P}^{j}\right) \beta+X^{j}
$$

with $X^{j} \in a_{H}$, the condition $\alpha\left(Y_{P}^{j}\right)>0$ is equivalent to

$$
\sum_{\beta \in \Delta_{P}-\{\alpha\}}\left(\tilde{\omega}_{\beta}^{P}, Y_{P}^{j}\right)[-(\beta, \alpha)]<\left(\tilde{\omega}_{\alpha}^{P}, Y_{P}^{j}\right)(\alpha, \alpha) .
$$

Since the real numbers $\left(\tilde{\omega}_{\beta}^{P}, Y_{P}^{j}\right)$, for $\beta \in \Delta_{P}$, and $-(\beta, \alpha)$, for $\alpha \neq \beta$ in $\Delta_{P}$, are
nonnegative, one deduces that:

$$
\begin{aligned}
& \sum_{\beta \in \Delta_{P}-\{\alpha\}}\left(\tilde{\omega}_{\beta}^{P}, Z_{P}\right)[-(\beta, \alpha)] \\
= & \sum_{\beta \in \Delta_{P}-\{\alpha\}} \inf \left(\left(\tilde{\omega}_{\beta}^{P}, Y_{P}^{1}\right),\left(\tilde{\omega}_{\beta}^{P}, Y_{P}^{2}\right)\right)[-(\beta, \alpha)] \\
\leqslant & \inf \left(\sum_{\beta \in \Delta_{P}-\{\alpha\}}\left(\tilde{\omega}_{\beta}^{P}, Y_{P}^{1}\right)[-(\beta, \alpha)], \sum_{\beta \in \Delta_{P}-\{\alpha\}}\left(\tilde{\omega}_{\beta}^{P}, Y_{P}^{2}\right)[-(\beta, \alpha)]\right) \\
< & \inf \left(\left(\tilde{\omega}_{\alpha}^{P}, Y_{P}^{1}\right),\left(\tilde{\omega}_{\alpha}^{P}, Y_{P}^{2}\right)\right)(\alpha, \alpha)=\left(\tilde{\omega}_{\alpha}^{P}, Z_{P}\right)(\alpha, \alpha) .
\end{aligned}
$$

This implies that $\alpha\left(Z_{P}\right)>0$ for $\alpha \in \Delta_{P}$, and thus $d(\mathcal{Z})>0$.
To get the property of the convex hulls, it is enough to prove that, for all $P \in$ $\mathcal{P}(M), a_{P}^{+} \cap \mathcal{S}_{M}\left(\mathcal{Y}^{1}\right) \cap \mathcal{S}_{M}\left(\mathcal{Y}^{2}\right)=a_{P}^{+} \cap \mathcal{S}_{M}(\mathcal{Z})$. By [Ar3, Lemma 3.1], one has:

$$
a_{P}^{+} \cap \mathcal{S}_{M}\left(\mathcal{Y}^{j}\right)=\left\{X \in a_{P}^{+} ; \omega_{\gamma}^{P}\left(X-Y_{P}^{j}\right) \leqslant 0, \gamma \in \Delta_{P}\right\} .
$$

Since $\tilde{\omega}_{\gamma}^{P}=c_{\gamma} \omega_{\gamma}^{P}$ for $\gamma \in \Delta_{P}$, where $c_{\gamma}$ is a positive real number, the assertion follows easily.

### 2.2 The truncated kernel

We consider the regular representation $R$ of $G \times G$ on $L^{2}(G)$ defined by

$$
\left(R\left(y_{1}, y_{2}\right) \phi\right)(x)=\phi\left(y_{1}^{-1} x y_{2}\right), \quad \phi \in L^{2}(G), y_{1}, y_{2} \in G
$$

Consider $f \in C_{c}^{\infty}(G \times G)$ of the form $f\left(y_{1}, y_{2}\right)=f_{1}\left(y_{1}\right) f_{2}\left(y_{2}\right)$ with $f_{1}, f_{2} \in C_{c}^{\infty}(G)$. Then

$$
R(f):=\int_{G} \int_{G} f_{1}\left(y_{1}\right) f_{2}\left(y_{2}\right) R\left(y_{1}, y_{2}\right) d y_{1} d y_{2}
$$

is an integral operator with smooth kernel

$$
K_{f}(x, y)=\int_{G} f_{1}(x g) f_{2}(g y) d g=\int_{G} f_{1}(g) f_{2}\left(x^{-1} g y\right) d g
$$

In our case (i.e. $H$ is split), one has $A_{H}=A_{G}$, and the kernel $K_{f}$ is invariant by the diagonal $\operatorname{diag}\left(A_{H}\right)$ of $A_{H}$ in $H \times H$. Since $H$ is not compact, we introduce truncation to integrate this kernel on $\operatorname{diag}\left(A_{H}\right) \backslash(H \times H)$.

We fix a point $T$ in $a_{0, \mathrm{~F}}$. Let $P_{0} \in \mathcal{P}\left(A_{0}\right)$. According to [Bou, Chap.5, Section 3, $n^{\circ}$ 3.3, Theorem 2], the closure $\bar{a}_{P_{0}}^{+}$of the positive Weyl chamber $a_{P_{0}}^{+}$is a fundamental domain of the Weyl group $W\left(H, A_{0}\right)$. We denote by $T_{P_{0}}$ the unique translate by the Weyl group $W\left(H, A_{0}\right)$ of $T$ in $\bar{a}_{P_{0}}^{+}$. Then

$$
\mathcal{Y}_{T}:=\left\{T_{P_{0}} ; P_{0} \in \mathcal{P}\left(A_{0}\right)\right\}
$$

is a $\left(H, A_{0}\right)$-orthogonal set. We shall assume that the number

$$
d(T):=\inf _{\alpha \in \Delta_{P_{0}}, P_{0} \in \mathcal{P}\left(A_{0}\right)} \alpha\left(T_{P_{0}}\right)
$$

is suitably large. This means that the distance from $T$ to any of the root hyperplanes in $a_{0}$ is large enough.

We denote by $u(\cdot, T)$ the characteristic function in $A_{H} \backslash H$ of the set of points $x$ such that

$$
\begin{equation*}
x=k_{1} a k_{2} \text { with } a \in A_{H} \backslash A_{0}, k_{1}, k_{2} \in K \text { and } h_{A_{0}}(a) \in \mathcal{S}_{A_{0}}\left(\mathcal{Y}_{T}\right), \tag{2.7}
\end{equation*}
$$

where $H=K A_{0} K$ is the Cartan decomposition of $H$.
We consider $u(\cdot, T)$ as an $A_{H}$-invariant function on $H$. Thus there is a compact set $\Omega_{T}$ of $H$ such that, if $u(x, T) \neq 0$, then $x \in A_{H} \Omega_{T}$. Let $\Omega$ be a compact subset of $G$ containing the support of $f_{1}$ and $f_{2}$. We consider $g \in G$ and $x_{1}, x_{2} \in H$ such that $f_{1}(g) f_{2}\left(x_{1}^{-1} g x_{2}\right) u\left(x_{1}, T\right) u\left(x_{2}, T\right) \neq 0$. Hence there are $\omega_{1}, \omega_{2}$ in $\Omega_{T}$ and $a_{1}, a_{2}$ in $A_{H}$ such that $x_{1}=\omega_{1} a_{1}, x_{2}=\omega_{2} a_{2}$ and we have $g \in \Omega$ and $x_{1}^{-1} g x_{2}=\omega_{1}^{-1} g \omega_{2} a_{1}^{-1} a_{2} \in \Omega$ since $A_{H}=A_{G}$. Therefore $a_{1}^{-1} a_{2}$ lies a compact subset of $A_{H}$. So then the map $\left(g, x_{1}, x_{2}\right) \mapsto f_{1}(g) f_{2}\left(x_{1}^{-1} g x_{2}\right) u\left(x_{1}, T\right) u\left(x_{2}, T\right)$ is a compactly supported function on $G \times \operatorname{diag}\left(A_{H}\right) \backslash(H \times H)$.
Hence we can define:

$$
K^{T}(f):=\int_{\operatorname{diag}\left(A_{H}\right) \backslash H \times H} K_{f}\left(x_{1}, x_{2}\right) u\left(x_{1}, T\right) u\left(x_{2}, T\right) \overline{d\left(x_{1}, x_{2}\right)}
$$

By Fubini's Theorem, we have:

$$
K^{T}(f)=\int_{G} \int_{\operatorname{diag}\left(A_{H}\right) \backslash H \times H} f_{1}(g) f_{2}\left(x_{1}^{-1} g x_{2}\right) u\left(x_{1}, T\right) u\left(x_{2}, T\right) \overline{d\left(x_{1}, x_{2}\right)} d g
$$

By applying the Weyl integration formula (1.33), we get that:

$$
\begin{equation*}
K^{T}(f)=\sum_{M \in \mathcal{L}\left(A_{0}\right)} c_{M} \sum_{S \in \mathcal{T}_{M}} \sum_{x_{m} \in \kappa_{S}} c_{S, x_{m}} \int_{S_{\sigma}} K^{T}\left(x_{m}, \gamma, f\right) d \gamma \tag{2.8}
\end{equation*}
$$

where, for $S \in \mathcal{T}_{M}, x_{m} \in \kappa_{S}$ and $\gamma \in S_{\sigma}, K^{T}\left(x_{m}, \gamma, f\right)$ is given by:

$$
\begin{gathered}
K^{T}\left(x_{m}, \gamma, f\right)=\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 2} \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} \int_{\operatorname{diag}\left(A_{H}\right) \backslash H \times H} f_{1}\left(y_{1}^{-1} x_{m} \gamma y_{2}\right) \\
\quad \times f_{2}\left(x_{1}^{-1} y_{1}^{-1} x_{m} \gamma y_{2} x_{2}\right) u\left(x_{1}, T\right) u\left(x_{2}, T\right) d \overline{\left(x_{1}, x_{2}\right)} d \overline{\left(y_{1}, y_{2}\right)} .
\end{gathered}
$$

Let us recall that, for any $S \in \mathcal{T}_{M}$, each $x_{m}$ in $\kappa_{S}$ and $\gamma$ in $S_{\sigma}$ commute with $A_{M}$. We first replace $\left(x_{1}, x_{2}\right)$ by $\left(y_{1} x_{1}, y_{2} x_{2}\right)$ in the integral over $\overline{\left(x_{1}, x_{2}\right)}$. The resulting integral over $\operatorname{diag}\left(A_{H}\right) \backslash H \times H$ can be expressed as a double integral over $a \in A_{H} \backslash A_{M}$
and $\left(x_{1}, x_{2}\right) \in \operatorname{diag}\left(A_{M}\right) \backslash H \times H$ which depends on $\overline{\left(y_{1}, y_{2}\right)} \in \operatorname{diag}\left(A_{M}\right) \backslash H \times H$. Since $A_{M}$ commutes with $x_{m} \in \kappa_{S}$ and $\gamma \in S_{\sigma}$, we obtain that:

$$
\begin{align*}
K^{T}\left(x_{m}, \gamma, f\right)=\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 2} & \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} f_{1}\left(y_{1}^{-1} x_{m} \gamma y_{2}\right) \\
& \times f_{2}\left(x_{1}^{-1} x_{m} \gamma x_{2}\right) u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) d \overline{\left(x_{1}, x_{2}\right)} d \overline{\left(y_{1}, y_{2}\right)} \tag{2.9}
\end{align*}
$$

$$
\text { where } u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)=\int_{A_{H} \backslash A_{M}} u\left(y_{1}^{-1} a x_{1}, T\right) u\left(y_{2}^{-1} a x_{2}, T\right) d a \text {. }
$$

Our goal is to prove that $K^{T}(f)$ is asymptotic to another integral $J^{T}(f)$, obtained similarly to $K^{T}(f)$, where the weight function $u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ is replaced by another weight function $v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ defined as follows.

We fix $M \in \mathcal{L}\left(A_{0}\right)$ and $P \in \mathcal{P}(M)$. Let $P_{0} \in \mathcal{P}\left(A_{0}\right)$, contained in $P$, and let $T_{P}$ be the projection of $T_{P_{0}}$ on $a_{M}$ with respect to the decomposition $a_{0}=a_{M} \oplus a_{0}^{M}$. From (2.2), the set $\mathcal{Y}_{M}(T):=\left\{T_{P} ; P \in \mathcal{P}(M)\right\}$ is a $(H, M)$-orthogonal set independent of the choice of $P_{0}$. Moreover, by [Ar3, equation (3.2)], we have $d\left(\mathcal{Y}_{M}(T)\right) \geqslant d(T)>0$. Thus $\mathcal{Y}_{M}(T)$ is a positive $(H, M)$-orthogonal set.

For $x, y$ in $H$, set

$$
Y_{P}(x, y, T):=T_{P}+h_{P}(y)-h_{\bar{P}}(x) .
$$

By [Ar3, p. 30], $\mathcal{Y}_{M}(x, y, T):=\left\{Y_{P}(x, y, T) ; P \in \mathcal{P}(M)\right\}$ is a $(H, M)$-orthogonal set, which is positive when $d(T)$ is sufficiently large relatively to $x$ and $y$.

For $x_{1}, x_{2}, y_{1}$ and $y_{2}$ in $H$, let

$$
\begin{equation*}
Z_{P}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right):=\inf ^{P}\left(Y_{P}\left(x_{1}, y_{1}, T\right), Y_{P}\left(x_{2}, y_{2}, T\right)\right) \tag{2.10}
\end{equation*}
$$

where $\inf ^{P}$ is defined in (2.6) and

$$
\begin{equation*}
\mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right):=\left\{Z_{P}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) ; P \in \mathcal{P}(M)\right\} . \tag{2.11}
\end{equation*}
$$

By Lemma 2.6, the set $\mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ is a $(H, M)$-orthogonal set. Moreover, when $d(T)$ is large relatively to $x_{i}, y_{i}$, for $i=1,2$, one has $d\left(\mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right)>$ 0 . Hence this set is a positive $(H, M)$-orthogonal set.

Let $v_{M}$ be the weight function defined by:

$$
\begin{equation*}
v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right):=\int_{A_{H} \backslash A_{M}} \sigma_{M}\left(h_{M}(a), \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right) d a \tag{2.12}
\end{equation*}
$$

where $\sigma_{M}$ is given by (2.4).
We set

$$
\begin{equation*}
J^{T}(f):=\sum_{M \in \mathcal{L}\left(A_{0}\right)} c_{M} \sum_{S \in \mathcal{T}_{M}} \sum_{x_{m} \in \kappa_{S}} c_{S, x_{m}} \int_{S_{\sigma}} J^{T}\left(x_{m}, \gamma, f\right) d \gamma, \tag{2.13}
\end{equation*}
$$

where

$$
\begin{array}{r}
J^{T}\left(x_{m}, \gamma, f\right)=\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 2} \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} f_{1}\left(y_{1}^{-1} x_{m} \gamma y_{2}\right)  \tag{2.14}\\
\quad \times f_{2}\left(x_{1}^{-1} x_{m} \gamma x_{2}\right) v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) d \overline{\left(x_{1}, x_{2}\right)} d \overline{\left(y_{1}, y_{2}\right)} .
\end{array}
$$

Our main result is the following. Its proof is postponed to Section 2.4.
2.3 Theorem. Let $\delta>0$. Then there are positive numbers $C$ and $\varepsilon$ such that, for all $T$ with $d(T) \geqslant \delta\|T\|$, one has:

$$
\begin{equation*}
\left|K^{T}(f)-J^{T}(f)\right| \leqslant C e^{-\varepsilon\|T\|} . \tag{2.15}
\end{equation*}
$$

### 2.3 Preliminaries to estimates

We fix a norm $\|\cdot\|$ on $G$ as in (1.15). Let $\mathrm{F}^{\prime}$ be a finite extension of F . We set $\underline{G^{\prime}}:=\underline{G} \times \mathrm{F} \mathrm{F}^{\prime}$ and $G^{\prime}:=\underline{G^{\prime}}\left(\mathrm{F}^{\prime}\right)$. One can extend the absolute value $|\cdot|_{\mathrm{F}}$ to $\mathrm{F}^{\prime}$ and the norm $\|\cdot\|$ to $G^{\prime}$. For $x, y$ in $G^{\prime}$, we set

$$
\|(x, y)\|:=\|x\|\|y\| .
$$

To obtain our estimates, we will use $\leqslant$ and $\approx$ defined respectively in (1.18) and (1.19). As the norm is expected to take values greater than or equal to 1 , we can freely apply the properties (1.20).
2.4 Lemma. Let $S$ be a maximal torus of $H$ and let $M$ be the centralizer of $A_{S}$ in $H$. We fix $x_{m} \in G \cap \underline{M S}_{\sigma}=\tilde{M} \cap \underline{M S}_{\sigma}$. Then one has:

$$
\begin{equation*}
\inf _{s \in S}\left\|\left(s x_{m}^{-1} x_{1}, s x_{2}\right)\right\| \leqslant \inf _{s^{\prime} \in \underline{S}\left(\mathrm{~F}^{\prime}\right)}\left\|\left(s^{\prime} x_{m}^{-1} x_{1}, s^{\prime} x_{2}\right)\right\|, \quad x_{1}, x_{2} \in H \tag{2.16}
\end{equation*}
$$

Proof. Since $H^{1} A_{H}$ is of finite index in $H$, we may assume, using (1.21), that $x_{1}$ and $x_{2}$ belong to $H^{1} A_{H}$. As $A_{G}=A_{H}$, using the invariance of the property (2.16) by the left action of $\operatorname{diag}\left(A_{H}\right)$ on $\left(x_{1}, x_{2}\right)$, it is enough to prove the result for $x_{1} \in H^{1}$ and $x_{2}=a_{2} y_{2}$ with $a_{2} \in A_{H}$ and $y_{2} \in H^{1}$.

To establish (2.16), we first assume that $A_{S}=A_{H}$, which implies that the quotient $A_{H} \backslash S$ is compact. By (1.21), there is a positive constant $C$ such that:

$$
\inf _{s \in S}\left\|\left(s x_{m}^{-1} x_{1}, s x_{2}\right)\right\| \leqslant C \inf _{a \in A_{H}}\left\|\left(a x_{m}^{-1} x_{1}, a x_{2}\right)\right\| .
$$

We deduce from (1.17) that:

$$
\left\|\left(a x_{m}^{-1} x_{1}, a x_{2}\right)\right\| \leqslant\left\|x_{m}^{-1}\right\|\|a\|^{2}\left\|a_{2}\right\|\left\|x_{1}\right\|\left\|y_{2}\right\|
$$

Taking the lower bound in $a \in A_{H}$, there is a positive constant $C_{1}$ such that:

$$
\begin{equation*}
\inf _{s \in S}\left\|\left(s x_{m}^{-1} x_{1}, s x_{2}\right)\right\| \leqslant C_{1}\left\|x_{1}\right\|\left\|a_{2}\right\|\left\|y_{2}\right\| . \tag{2.17}
\end{equation*}
$$

In the following, we will need [Ar3, Lemma 4.1] that we recall here.
If $S_{0}$ is a maximal torus of $H$ with $A_{H} \backslash S_{0}$ compact, then there exists an element $s_{0} \in S_{0}$ such that:

$$
\begin{equation*}
\|y\| \leqslant\left\|y^{-1} s_{0} y\right\|, \quad y \in H^{1} . \tag{2.18}
\end{equation*}
$$

On one hand, we apply this result to $S_{0}=S$. As $\underline{S}\left(\mathrm{~F}^{\prime}\right)$ commutes with $s_{0}$, one deduces, using the property (1.17) of the norm, that:

$$
\begin{equation*}
\left\|y_{2}\right\| \leqslant\left\|s^{\prime} y_{2}\right\|^{2}\left\|s_{0}\right\|, \quad y_{2} \in H^{1}, s^{\prime} \in \underline{S}\left(\mathrm{~F}^{\prime}\right) . \tag{2.19}
\end{equation*}
$$

On the other hand, as $x_{m} \in G \cap \underline{M S_{\sigma}}, S_{1}:=x_{m} S x_{m}^{-1}$ is a maximal torus of $H$ which satisfies $A_{S_{1}}=A_{H}$. Applying (2.18) to $S_{0}=S_{1}$, there exists $s_{1} \in S$ such that:

$$
\begin{equation*}
\left\|x_{1}\right\| \leqslant\left\|x_{1}^{-1} x_{m} s_{1} x_{m}^{-1} x_{1}\right\|, \quad x_{1} \in H^{1} \tag{2.20}
\end{equation*}
$$

The same argument as above leads to:

$$
\begin{equation*}
\left\|x_{1}\right\| \leqslant\left\|s^{\prime} x_{m}^{-1} x_{1}\right\|^{2}\left\|s_{1}\right\|, \quad x_{1} \in H^{1}, s^{\prime} \in \underline{S}\left(\mathrm{~F}^{\prime}\right) . \tag{2.21}
\end{equation*}
$$

Then, by (2.17), (2.19) and (2.21), and applying the properties (1.20), we deduce that:

$$
\begin{align*}
\inf _{s \in S}\left\|\left(s x_{m}^{-1} x_{1}, s a_{2} y_{2}\right)\right\| \leqslant & \left\|s^{\prime} x_{m}^{-1} x_{1}\right\|\left\|s^{\prime} y_{2}\right\|\left\|a_{2}\right\|,  \tag{2.22}\\
& s^{\prime} \in \underline{S}\left(\mathrm{~F}^{\prime}\right), x_{1}, y_{2} \in H^{1}, a_{2} \in A_{H} .
\end{align*}
$$

To obtain our result, we have to prove that:

$$
\begin{equation*}
\left\|s^{\prime} x_{m}^{-1} x_{1}\right\|\left\|s^{\prime} y_{2}\right\|\left\|a_{2}\right\| \leqslant\left\|\left(s^{\prime} x_{m}^{-1} x_{1}, s^{\prime} a_{2} y_{2}\right)\right\|, \quad s^{\prime} \in \underline{S}\left(\mathrm{~F}^{\prime}\right), x_{1}, y_{2} \in H^{1}, a_{2} \in A_{H} . \tag{2.23}
\end{equation*}
$$

We can write $\underline{S}=\underline{T} A_{H}$ where $\underline{T}$ is a maximal torus of the derived group $\underline{H}_{d e r}$ of $\underline{H}$. We set $T^{\prime}:=\underline{T}\left(\mathrm{~F}^{\prime}\right)$ and $A_{H}^{\prime}:=\underline{A}_{H}\left(\mathrm{~F}^{\prime}\right)$. Then $T^{\prime}$ is contained in $H^{\prime 1}$. Moreover, the intersection of $\underline{T}$ and $\underline{A}_{H}$ is finite. Hence, one has the exact sequence:

$$
1 \rightarrow \underline{T} \cap \underline{A}_{H} \rightarrow \underline{T} \times \underline{A}_{H} \rightarrow \underline{S} \rightarrow 1
$$

Going to $\mathrm{F}^{\prime}$-points, the long exact sequence in cohomology implies that $T^{\prime} A_{H}^{\prime}$ is of finite index in $\underline{S}\left(\mathrm{~F}^{\prime}\right)$. Thus, by (1.21), it is enough to prove (2.23) for $s^{\prime}=t^{\prime} a^{\prime} \in$ $\underline{S}\left(\mathrm{~F}^{\prime}\right)$ with $t^{\prime} \in T^{\prime}$ and $a^{\prime} \in A_{H}^{\prime}$. By (1.5), if $x_{1} \in H^{1}$, then $x_{1} \in H^{\prime 1} \subset G^{\prime 1}$ and $x_{m}^{-1} x_{1} x_{m} \in G^{\prime 1}$. As $H$ is split, we have $A_{H}^{\prime}=A_{G}^{\prime}$. Then (1.23) gives

$$
\left\|a^{\prime} t^{\prime} x_{m}^{-1} x_{1}\right\| \approx\left\|a^{\prime} t^{\prime} x_{m}^{-1} x_{1} x_{m}\right\| \approx\left\|a^{\prime}\right\|\left\|t^{\prime} x_{m}^{-1} x_{1} x_{m}\right\|, \quad a^{\prime} \in A_{H}^{\prime}, t^{\prime} \in T^{\prime}, x_{1} \in H^{1}
$$

and

$$
\left\|a^{\prime} t^{\prime} y_{2}\right\| \approx\left\|a^{\prime}\right\|\left\|t^{\prime} y_{2}\right\|, \quad a^{\prime} \in A_{H}^{\prime}, t^{\prime} \in T^{\prime}, y_{2} \in H^{1}
$$

Applying (1.20), we deduce that:

$$
\begin{align*}
\left\|t^{\prime} a^{\prime} x_{m}^{-1} x_{1}\right\|\left\|a^{\prime} t^{\prime} y_{2}\right\|\left\|a_{2}\right\| \approx & \left\|a_{2}\right\|\left\|a^{\prime}\right\|^{2}\left\|t^{\prime} x_{m}^{-1} x_{1} x_{m}\right\|\left\|t^{\prime} y_{2}\right\| \\
\approx & \left\|a_{2}\right\|\left\|a^{\prime}\right\|\left\|t^{\prime} x_{m}^{-1} x_{1} x_{m}\right\|\left\|t^{\prime} y_{2}\right\|,  \tag{2.24}\\
& t^{\prime} \in T^{\prime}, a^{\prime} \in A_{H}^{\prime}, x_{1}, y_{2} \in H^{1}, a_{2} \in A_{H} .
\end{align*}
$$

Let us prove that:

$$
\begin{equation*}
\left\|a^{\prime}\right\|\left\|a^{\prime} a_{2}\right\| \approx\left\|a^{\prime}\right\|\left\|a_{2}\right\|, \quad a^{\prime} \in A_{H}^{\prime}, a_{2} \in A_{H} \tag{2.25}
\end{equation*}
$$

According to (1.17), one has $\left\|a^{\prime} a_{2}\right\| \leqslant\left\|a^{\prime}\right\|\left\|a_{2}\right\|$. Then $\left\|a^{\prime}\right\|\left\|a^{\prime} a_{2}\right\| \leqslant\left(\left\|a^{\prime}\right\|\left\|a_{2}\right\|\right)^{2}$, as $1 \leqslant\left\|a_{2}\right\|$. Since $\left\|a^{\prime}\right\|=\left\|a^{\prime} a_{2} a_{2}^{-1}\right\| \leqslant\left\|a^{\prime} a_{2}\right\|\left\|a_{2}\right\|$, we have $\left\|a^{\prime}\right\|\left\|a_{2}\right\| \leqslant\left(\left\|a^{\prime} a_{2}\right\|\left\|a_{2}\right\|\right)^{2}$ and (2.25) follows. Applying (2.25) in (2.24), we deduce that:

$$
\begin{align*}
\left\|t^{\prime} a^{\prime} x_{m}^{-1} x_{1}\right\|\left\|a^{\prime} t^{\prime} y_{2}\right\|\left\|a_{2}\right\| \leqslant & \left\|a^{\prime}\right\|\left\|t^{\prime} x_{m}^{-1} x_{1} x_{m}\right\|\left\|a^{\prime} a_{2}\right\|\left\|t^{\prime} y_{2}\right\|, \\
& t^{\prime} \in T^{\prime}, a^{\prime} \in A_{H}^{\prime}, x_{1}, y_{2} \in H^{1}, a_{2} \in A_{H} . \tag{2.26}
\end{align*}
$$

As $x_{m}^{-1} H^{1} x_{m} \subset G^{\prime 1}$ and $A_{H}^{\prime}=A_{G}^{\prime}$, we obtain from (1.23) that:

$$
\left\|a^{\prime}\right\|\left\|t^{\prime} x_{m}^{-1} x_{1} x_{m}\right\| \approx\left\|a^{\prime} t^{\prime} x_{m}^{-1} x_{1} x_{m}\right\| \approx\left\|a^{\prime} t^{\prime} x_{m}^{-1} x_{1}\right\|, \quad a^{\prime} \in A_{H}^{\prime}, t^{\prime} \in T^{\prime}, x_{1} \in H^{1}
$$

and

$$
\left\|a^{\prime} a_{2}\right\|\left\|t^{\prime} y_{2}\right\| \approx\left\|a^{\prime} a_{2} t^{\prime} y_{2}\right\|, \quad a^{\prime} \in A_{H}^{\prime}, t^{\prime} \in T^{\prime}, a_{2} \in A_{H}, y_{2} \in H^{1}
$$

Applying this in (2.26) and using (1.20), we deduce that:

$$
\left\|t^{\prime} a^{\prime} x_{m}^{-1} x_{1}\right\|\left\|a^{\prime} t^{\prime} y_{2}\right\|\left\|a_{2}\right\| \leqslant\left\|a^{\prime} t^{\prime} x_{m}^{-1} x_{1}\right\|\left\|a^{\prime} t^{\prime} a_{2} y_{2}\right\|, \quad a^{\prime} \in A_{H}^{\prime}, t^{\prime} \in T^{\prime}, x_{1}, y_{2} \in H^{1}
$$

Then the property (2.23) follows. This finishes the proof of the Lemma when $A_{H} \backslash S$ is compact.

We now prove (2.16) for any maximal torus $S$ of $H$. Let $A_{S}$ be the maximal split torus of $S$ and let $M$ be the centralizer of $A_{S}$ in $H$. Thus we have $A_{M}=A_{S}$ and $A_{M} \backslash S$ is compact. Let $P=M N_{P} \in \mathcal{P}(M)$ and let $K$ be a compact subgroup of $H$ such that $H=P K$. Each $x \in H$ can be written $x=m_{P}(x) n_{P}(x) k(x)$ with $m_{P}(x) \in M, n_{P}(x) \in N_{P}$ and $k(x) \in K$. Then there is a positive constant $C$ such that:

$$
\begin{align*}
& \inf _{s \in S}\left\|\left(s x_{m}^{-1} x_{1}, s x_{2}\right)\right\| \\
\leqslant & C \inf _{s \in S}\left(\left\|s x_{m}^{-1} m_{P}\left(x_{1}\right)\right\|\left\|s m_{P}\left(x_{2}\right)\right\|\right)\left\|n_{P}\left(x_{1}\right)\right\|\left\|n_{P}\left(x_{2}\right)\right\|, \quad x_{1}, x_{2} \in H . \tag{2.27}
\end{align*}
$$

By assumption on $x_{m}$, there exist $h_{m} \in \underline{M}$ and $a_{m} \in \underline{S}_{\sigma}$ such that $x_{m}=h_{m} a_{m} \in \tilde{M}$. Hence we can apply the first part of the proof to $(M, S)$ instead of $(H, S)$. Therefore, we obtain:

$$
\begin{array}{r}
\inf _{s \in S}\left\|\left(s x_{m}^{-1} x_{1}, s x_{2}\right)\right\| \leqslant \inf _{s^{\prime} \in \underline{S}\left(\mathrm{~F}^{\prime}\right)}\left(\left\|s^{\prime} x_{m}^{-1} m_{P}\left(x_{1}\right)\right\|\left\|s^{\prime} m_{P}\left(x_{2}\right)\right\|\right)\left\|n_{P}\left(x_{1}\right)\right\|\left\|n_{P}\left(x_{2}\right)\right\|, \\
x_{1}, x_{2} \in H
\end{array}
$$

To compare the right hand-side of this inequality to the one of (2.16), we will use the Iwasawa decomposition (1.12) of $H^{\prime}$. Let $K^{\prime}$ be a compact subgroup of $H^{\prime}$ such that $H^{\prime}=\underline{P}\left(\mathrm{~F}^{\prime}\right) K^{\prime}=\underline{M}\left(\mathrm{~F}^{\prime}\right) \underline{N}_{P}\left(\mathrm{~F}^{\prime}\right) K^{\prime}$. According to (1.13), each $y$ in $H^{\prime}$ can be written $y=m_{P}^{\prime}(y) n_{P}^{\prime}(y) k^{\prime}$ with $m_{P}^{\prime}(y) \in \underline{M}\left(\mathrm{~F}^{\prime}\right), n_{P}^{\prime}(y) \in \underline{N}_{P}\left(\mathrm{~F}^{\prime}\right)$ and $k^{\prime} \in K^{\prime}$. Then, for $x \in H$ and $z \in \underline{M}\left(\mathrm{~F}^{\prime}\right)$, we have $z x=z m_{P}(x) n_{P}(x) k=m_{P}^{\prime}(z x) n_{P}^{\prime}(z x) k^{\prime}$ with $k \in$ and $k^{\prime} \in K^{\prime}$. Hence, as $K$ and $K^{\prime}$ are compact subsets, there is a positive constant $C^{\prime}$ such that:

$$
\left\|n_{P}^{\prime}(z x)^{-1} m_{P}^{\prime}(z x)^{-1} z m_{P}(x) n_{P}(x)\right\| \leqslant C^{\prime}, \quad z \in \underline{M}\left(\mathrm{~F}^{\prime}\right), x \in H .
$$

Since $z m_{p}(x) \in \underline{M}\left(\mathrm{~F}^{\prime}\right)$ for $z \in \underline{M}\left(\mathrm{~F}^{\prime}\right)$ and $x \in H$, we deduce from (1.22) that there is a positive constant $C_{1}$ such that, for $x \in H$ and $z \in \underline{M}\left(\mathrm{~F}^{\prime}\right)$, one has:

$$
\left\|n_{P}^{\prime}(z x)^{-1} m_{P}^{\prime}(z x)^{-1} z m_{P}(x) n_{P}^{\prime}(z x)\right\| \leqslant C_{1} \quad \text { and } \quad\left\|n_{P}^{\prime}(z x)^{-1} n_{P}(x)\right\| \leqslant C_{1}
$$

By (1.17), we obtain:

$$
\left\|z m_{P}(x)\right\| \leqslant C_{1}\left\|m_{P}^{\prime}(z x)\right\|\left\|n_{P}^{\prime}(z x)\right\|^{2} \quad \text { and } \quad\left\|n_{P}(x)\right\| \leqslant C_{1}\left\|n_{P}^{\prime}(z x)\right\| .
$$

Using again (1.22), it follows that:

$$
\left\|z m_{P}(x)\right\| \leqslant\|z x\|, \quad \text { and }\left\|n_{P}(x) \mid \leqslant\right\| z x \|, \quad z \in \underline{M}\left(\mathrm{~F}^{\prime}\right), x \in H
$$

Hence, by (1.20),

$$
\begin{equation*}
\left\|z m_{P}(x)\right\|\left\|n_{P}(x) \mid \leqslant\right\| z x \|, \quad z \in \underline{M}\left(\mathrm{~F}^{\prime}\right), x \in H . \tag{2.28}
\end{equation*}
$$

We deduce that:

$$
\begin{equation*}
\left\|s^{\prime} m_{P}\left(x_{2}\right)\right\|\left\|n_{P}\left(x_{2}\right) \mid \leqslant\right\| s^{\prime} x_{2} \|, \quad s^{\prime} \in \underline{S}\left(\mathrm{~F}^{\prime}\right), x_{2} \in H . \tag{2.29}
\end{equation*}
$$

Since $x_{m}=h_{m} a_{m}$ with $h_{m} \in \underline{M}$ and $a_{m} \in \underline{S}_{\sigma}$, one has $x_{m} s^{\prime} x_{m}^{-1} \in \underline{M} \cap H^{\prime}=\underline{M}\left(\mathrm{~F}^{\prime}\right)$ for $s^{\prime} \in \underline{S}\left(\mathrm{~F}^{\prime}\right)$. Therefore, we deduce from (2.28) that:

$$
\begin{equation*}
\left\|x_{m} s^{\prime} x_{m}^{-1} m_{P}\left(x_{1}\right)\right\|\left\|n_{P}\left(x_{1}\right) \mid \leqslant\right\| x_{m} s^{\prime} x_{m}^{-1} x_{1} \|, \quad s^{\prime} \in \underline{S}\left(\mathrm{~F}^{\prime}\right), x_{1} \in H . \tag{2.30}
\end{equation*}
$$

Since $\left\|s^{\prime} x_{m}^{-1} m_{P}\left(x_{1}\right)\right\| \leqslant\left\|x_{m}^{-1}\right\|\left\|x_{m} s^{\prime} x_{m}^{-1} m_{P}\left(x_{1}\right)\right\|$ and $\left\|x_{m} s^{\prime} x_{m}^{-1} x_{1}\right\| \leqslant\left\|x_{m}\right\| s^{\prime} x_{m}^{-1} x_{1} \|$, we deduce the estimate (2.16) from (2.27), (2.29) and (2.30). This finishes the proof of the Lemma.

The following Lemma is the analogue of [Ar3, Lemma 4.2].
2.5 Lemma. Let $S$ be a maximal torus of $H$ and let $x_{m} \in \kappa_{S}$. Then there is a positive integer $k$ with the property that, for any given compact subset $\Omega$ of $G$, there exists a positive constant $C_{\Omega}$ such that, for all $\gamma \in S_{\sigma}$, with $x_{m} \gamma \in G^{\sigma-r e g}$, and all $x_{1}, x_{2}$ in $H$ satisfying $x_{1}^{-1} x_{m} \gamma x_{2} \in \Omega$, one has:

$$
\inf _{s \in S}\left\|\left(s x_{m}^{-1} x_{1}, s x_{2}\right)\right\| \leqslant C_{\Omega}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{-k}
$$

Proof. Let $\mathrm{F}^{\prime}$ be a finite extension of E such that $\underline{\tilde{S}}$ splits over $\mathrm{F}^{\prime}$. Recall that we can write $x_{m}=h_{m} a_{m}$ with $h_{m} \in \underline{H}$ and $a_{m} \in \underline{S}_{\sigma}$. Thus we may and will choose $\mathrm{F}^{\prime}$ such that $h_{m} \in \underline{H}\left(\mathrm{~F}^{\prime}\right)$ and $a_{m} \in \underline{S}_{\sigma}\left(\mathrm{F}^{\prime}\right)$. For convenience, if $\underline{J}$ is an algebraic variety defined over F , we set $J^{\prime}:=\underline{J}\left(\mathrm{~F}^{\prime}\right)$.

According to the previous Lemma 2.4, it is enough to prove the existence of a positive integer $k$ satisfying the property that, for any compact subset $\Omega^{\prime}$ of $G^{\prime \sigma-r e g}$, there exists $C_{\Omega^{\prime}}>0$ such that:

$$
\begin{equation*}
\inf _{s^{\prime} \in S^{\prime}}\left(\left\|s^{\prime} x_{m}^{-1} x_{1}\right\|\left\|s^{\prime} x_{2}\right\|\right) \leqslant C_{\Omega^{\prime}}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{F}^{-k} \tag{2.31}
\end{equation*}
$$

for all $x_{1}, x_{2} \in H^{\prime}$ and $\gamma \in S_{\sigma}$ satisfying $x_{m} \gamma \in G^{\sigma-r e g}$ and $x_{1}^{-1} x_{m} \gamma x_{2} \in \Omega^{\prime}$.
Let $B^{\prime}=S^{\prime} N^{\prime}$ be a Borel subgroup of $H^{\prime}$ containing $S^{\prime}$ and $K^{\prime}$ be a compact subgroup of $H^{\prime}$ such that $H^{\prime}=S^{\prime} N^{\prime} K^{\prime}=N^{\prime} S^{\prime} K^{\prime}$. We can also write $H^{\prime}=\left(h_{m} S^{\prime} h_{m}^{-1}\right)\left(h_{m} N^{\prime} h_{m}^{-1}\right)\left(h_{m} K^{\prime} h_{m}^{-1}\right)$. By (1.21), one can reduce the proof to the statement for $x_{1} \in\left(h_{m} S^{\prime} h_{m}^{-1}\right)\left(h_{m} N^{\prime} h_{m}^{-1}\right)$ and $x_{2} \in S^{\prime} N^{\prime}$.

Let $x_{1}=h_{m} s_{1} n_{1} h_{m}^{-1}$ and $x_{2}=s_{1} s_{2} n_{2}$ with $s_{1}, s_{2} \in S^{\prime}$ and $n_{1}, n_{2} \in N^{\prime}$. Since $x_{m}=h_{m} a_{m}$, we have $x_{m} s_{1} x_{m}^{-1}=h_{m} s_{1} h_{m}^{-1}$. Hence, for any $s^{\prime} \in S^{\prime}$, we have $s^{\prime} x_{m}^{-1} x_{1}=$ $s^{\prime} x_{m}^{-1} x_{m} s_{1} x_{m}^{-1} h_{m} n_{1} h_{m}^{-1}=s^{\prime} s_{1} x_{m}^{-1} h_{m} n_{1} h_{m}^{-1}$. We thus obtain:

$$
\inf _{s^{\prime} \in S^{\prime}}\left(\left\|s^{\prime} x_{m}^{-1} x_{1}\right\|\left\|s^{\prime} x_{2}\right\|\right)=\inf _{s^{\prime} \in S^{\prime}}\left(\left\|s^{\prime} x_{m}^{-1} h_{m} n_{1} h_{m}^{-1}\right\|\left\|s^{\prime} s_{2}\right\|\right)
$$

Notice that $x_{1}^{-1} x_{m} \gamma x_{2}=h_{m} n_{1}^{-1} h_{m}^{-1} x_{m} s_{1}^{-1} x_{m}^{-1} x_{m} \gamma s_{1} s_{2} n_{2}=h_{m} n_{1}^{-1} h_{m}^{-1} x_{m} \gamma s_{2} n_{2}$.
Therefore, we are reduced to prove (2.31) for $x_{1}=h_{m} n_{1} h_{m}^{-1}$ with $n_{1} \in N^{\prime}$, $x_{2}=s_{2} n_{2}$ with $n_{2} \in N^{\prime}, s_{2} \in S^{\prime}$ and $\gamma \in S_{\sigma}$ such that $x_{m} \gamma$ is $\sigma$-regular and $x_{1}^{-1} x_{m} \gamma x_{2} \in \Omega^{\prime}$. By the properties of the norm, there is some positive constant $C^{\prime}$ such that:

$$
\begin{equation*}
\inf _{s^{\prime} \in S^{\prime}}\left(\left\|s^{\prime} x_{m}^{-1} x_{1}\right\|\left\|s^{\prime} x_{2}\right\|\right) \leqslant C^{\prime}\left\|n_{1}\right\|\left\|s_{2}\right\|\left\|n_{2}\right\|, \quad x_{1}=h_{m} n_{1} h_{m}^{-1}, x_{2}=s_{2} n_{2} \tag{2.32}
\end{equation*}
$$

We want to estimate $\left\|n_{1}\right\|\left\|s_{2}\right\|\left\|n_{2}\right\|$ when $x_{1}=h_{m} n_{1} h_{m}^{-1}$ and $x_{2}=s_{2} n_{2}$ satisfy $x_{1}^{-1} x_{m} \gamma x_{2} \in \Omega^{\prime}$. For this, we use the isomorphism $\Psi$ from $G^{\prime}$ to $H^{\prime} \times H^{\prime}$ defined in (1.26). If $x \in H^{\prime}$, then $\Psi(x)=(x, x)$ and, if $y \in G$ satisfies $y^{-1}=\sigma(y)$, then $\Psi(y)=\left(y, y^{-1}\right)$. We set $\left(y_{1}, y_{2}\right):=\Psi\left(x_{1}^{-1} x_{m} \gamma x_{2}\right)$. Then we have:

$$
y_{1}=h_{m} n_{1}^{-1} a_{m} \gamma n_{2} s_{2}=h_{m}\left(n_{1}^{-1} a_{m} \gamma n_{2}\left(a_{m} \gamma\right)^{-1}\right)\left(a_{m} \gamma s_{2}\right)
$$

and

$$
y_{2}=h_{m} n_{1}^{-1} a_{m}^{-1} \gamma^{-1} n_{2} s_{2}=h_{m}\left(n_{1}^{-1} a_{m}^{-1} \gamma^{-1} n_{2} \gamma a_{m}\right)\left(a_{m} \gamma\right)^{-1} s_{2} .
$$

Since $H^{\prime}=N^{\prime} S^{\prime} K^{\prime}$, the condition $x_{1}^{-1} x_{m} \gamma x_{2} \in \Omega^{\prime}$ implies that there exist two compact subsets $\Omega_{N} \subset N^{\prime}$ and $\Omega_{S} \subset S^{\prime}$ depending only on $\Omega^{\prime}$ such that:

$$
\begin{aligned}
& n_{1}^{-1} a_{m} \gamma n_{2}\left(a_{m} \gamma\right)^{-1} \in \Omega_{N}, \quad n_{1}^{-1} a_{m}^{-1} \gamma^{-1} n_{2} \gamma a_{m} \in \Omega_{N}, \\
& a_{m} \gamma s_{2} \in \Omega_{S} \quad \text { and } \quad\left(a_{m} \gamma\right)^{-1} s_{2} \in \Omega_{S} .
\end{aligned}
$$

We deduce from the second property that $s_{2}$ and $\gamma$ must lie in compact subsets of $S^{\prime}$. We set

$$
\nu_{1}\left(\gamma, n_{1}, n_{2}\right):=n_{1}^{-1} a_{m} \gamma n_{2}\left(a_{m} \gamma\right)^{-1} \quad \text { and } \quad \nu_{2}\left(\gamma, n_{1}, n_{2}\right):=n_{1}^{-1}\left(a_{m} \gamma\right)^{-1} n_{2} a_{m} \gamma .
$$

We consider the map $\psi$ from $N^{\prime} \times N^{\prime}$ into itself defined by $\psi\left(n_{1}, n_{2}\right)=\left(\nu_{1}, \nu_{2}\right)$. Recall that $\Phi\left(S^{\prime}, \mathfrak{h}^{\prime}\right)$ denotes the set of roots of $S^{\prime}$ in the Lie algebra $\mathfrak{h}^{\prime}$ of $H^{\prime}$ (cf. (1.27)). Let $\mathfrak{n}^{\prime}$ be the Lie algebra of $N^{\prime}$. For $\alpha \in \Phi\left(S^{\prime}, \mathfrak{h}^{\prime}\right)$, we denote by $X_{\alpha} \in \mathfrak{n}^{\prime}$ the root vector in $\mathfrak{h}^{\prime}$ corresponding to $\alpha$. Then $a_{m} \gamma$ acts on $X_{\alpha}$ by $a_{\alpha}:=\left(a_{m} \gamma\right)^{\alpha}$. The differential $d_{\left(n_{1}, n_{2}\right)} \psi$ of $\psi$ at $\left(n_{1}, n_{2}\right) \in N^{\prime} \times N^{\prime}$ is given by $d_{\left(n_{1}, n_{2}\right)} \psi\left(X_{1}, X_{2}\right)=$ $\left(\operatorname{Ad}\left(a_{m} \gamma n_{2}^{-1}\left(a_{m} \gamma\right)^{-1}\right) Y_{1}, \operatorname{Ad}\left(\left(a_{m} \gamma\right)^{-1} n_{2}^{-1} a_{m} \gamma\right) Y_{2}\right)$, where

$$
Y_{1}=-\operatorname{Ad}\left(n_{1}\right) X_{1}+\operatorname{Ad}\left(a_{m} \gamma\right) \operatorname{Ad}\left(n_{2}\right) X_{2}
$$

and

$$
Y_{2}=-\operatorname{Ad}\left(n_{1}\right) X_{1}+\operatorname{Ad}\left(a_{m} \gamma\right)^{-1} \operatorname{Ad}\left(n_{2}\right) X_{2}
$$

The map $\left(X_{1}, X_{2}\right) \mapsto\left(Y_{1}, Y_{2}\right)$ is the composition of the map $\left(X_{1}, X_{2}\right) \mapsto$ $\left(\operatorname{Ad}\left(n_{1}\right) X_{1}, \operatorname{Ad}\left(n_{2}\right) X_{2}\right)$, whose determinant is equal to 1 , with $d_{e} \psi$, where $e$ is the neutral point of $N^{\prime} \times N^{\prime}$. We deduce that the jacobian of $\psi$ at $\left(n_{1}, n_{2}\right)$ is independent of $\left(n_{1}, n_{2}\right)$. At the neutral point $e \in N^{\prime} \times N^{\prime}$, we have $d_{e} \psi\left(X_{\alpha}, 0\right)=\left(-X_{\alpha},-X_{\alpha}\right)$ and $d_{e} \psi\left(0, X_{\alpha}\right)=\left(a_{\alpha} X_{\alpha}, a_{-\alpha} X_{\alpha}\right)$. Hence, the jacobian of $\psi$ is equal to:

$$
\begin{aligned}
\left|\prod_{\alpha \in \Phi\left(S^{\prime}, \mathfrak{h}^{\prime}\right)} a_{\alpha}\left(1-a_{-2 \alpha}\right)\right|_{F^{\prime}} & =\left|\operatorname{det}\left(\operatorname{Ad}\left(a_{m} \gamma\right)\right)_{\mathfrak{h}^{\prime} / \mathfrak{s}^{\prime}}\right|_{F^{\prime}}\left|\operatorname{det}\left(1-\operatorname{Ad}\left(a_{m} \gamma\right)^{-2}\right)_{\mathfrak{h}^{\prime} / \mathfrak{s}^{\prime}}\right| F_{F^{\prime}} \\
& =\left|D_{H^{\prime}}\left(\left(a_{m} \gamma\right)^{-2}\right)\right|_{F^{\prime}} .
\end{aligned}
$$

Recall that $x_{m} \gamma$ is assumed to be $\sigma$-regular. Thus, by (1.29), one has $\Delta_{\sigma}\left(x_{m} \gamma\right)=$ $D_{H^{\prime}}\left(a_{m}^{-2} \gamma^{-2}\right) \neq 0$. Then, arguing as in [HC2, proof of Lemma 10 and Lemma 11], we deduce that the map $\psi$ is an $\mathrm{F}^{\prime}$-rational isomorphism of $\underline{N} \times \underline{N}$ onto itself whose inverse $\left(\nu_{1}, \nu_{2}\right) \mapsto\left(n_{1}, n_{2}\right):=\left(n_{1}\left(\gamma, \nu_{1}, \nu_{2}\right), n_{2}\left(\gamma, \nu_{1}, \nu_{2}\right)\right)$ is rational. Moreover, there is a positive integer $k$ such that the map

$$
\left(y, \nu_{1}, \nu_{2}\right) \mapsto D_{\underline{H}}(y)^{k}\left(n_{1}\left(y, \nu_{1}, \nu_{2}\right), n_{2}\left(y, \nu_{1}, \nu_{2}\right)\right)
$$

is defined by an $\mathrm{F}^{\prime}$-rational morphism between the algebraic varieties $\underline{S} \times \underline{N} \times \underline{N}$ and $\underline{N} \times \underline{N}$. Since $\nu_{1}, \nu_{2}$ and $\gamma$ lie in compact subsets depending only on $\Omega^{\prime}$, one deduces that there exists a constant $C_{\Omega^{\prime}}>0$ such that:

$$
\left\|\left(n_{1}\left(\gamma, \nu_{1}, \nu_{2}\right), n_{2}\left(\gamma, \nu_{1}, \nu_{2}\right)\right)\right\| \leqslant C_{\Omega^{\prime}}\left|D_{H^{\prime}}\left(a_{m}^{-2} \gamma^{-2}\right)\right|_{\mathrm{F}^{\prime}}^{-k}=C_{\Omega^{\prime}}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{-k}
$$

The Lemma then follows from (2.32) and the fact that $s_{2}$ lies in a compact set.

### 2.4 Proof of Theorem 2.3

Our goal is to prove that $\left|K^{T}(f)-J^{T}(f)\right|$ is bounded by a function which approaches 0 as $T$ approaches infinity. By definition, $K^{T}(f)$ and $J^{T}(f)$ are finite linear combinations of $\int_{S_{\sigma}} K^{T}\left(x_{m}, \gamma, f\right) d \gamma$ and $\int_{S_{\sigma}} J^{T}\left(x_{m}, \gamma, f\right) d \gamma$ respectively, where $M \in \mathcal{L}\left(A_{0}\right)$, $S$ is a maximal torus of $M$ satisfying $A_{S}=A_{M}$ and $x_{m} \in \kappa_{S}$ (cf. (2.8) and (2.13)).

We fix $M \in \mathcal{L}\left(A_{0}\right)$ and a maximal torus $S$ of $M$ such that $A_{S}=A_{M}$. Let $x_{m} \in \kappa_{S}$. To obtain our result, it is enough to establish the estimate (2.15) for $\int_{S_{\sigma}}\left|K^{T}\left(x_{m}, \gamma, f\right)-J^{T}\left(x_{m}, \gamma, T\right)\right| d \gamma$. This will be done in Corollary 2.9 below.

For $\varepsilon>0$, we define

$$
\begin{equation*}
S_{\sigma}(\varepsilon, T):=\left\{\gamma \in S_{\sigma} ; 0<\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{F} \leqslant e^{-\varepsilon\|T\|}\right\} \tag{2.33}
\end{equation*}
$$

### 2.6 Lemma.

1. There exists $\varepsilon_{0}>0$ such that the map $\gamma \mapsto\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{\varepsilon_{0}}$ is locally integrable on $S_{\sigma}$.
2. Let $\varepsilon>0$. Let $B$ be a bounded subset of $S_{\sigma}$ and $p$ be a nonnegative integer. Then there is a positive constant $C_{B, p}$ depending on $B$ and $p$, such that:

$$
\left.\left.\int_{S_{\sigma}(\varepsilon, T) \cap B}|\log | \Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}} ^{-1}\right|^{p} d \gamma \leqslant C_{B, p} e^{-\frac{\varepsilon \varepsilon_{0}\|T\|}{2}}
$$

Proof. The proof of 1. follows from the one of the group case (cf. [HC3, Lemma 43]). We use the similar statement on Lie algebras and the exponential map. We denote by $\mathfrak{s}$ the Lie algebra of $S$. For $X \in \mathfrak{s}$, we set $\eta(X)=\left|\operatorname{det}(\operatorname{ad} X)_{\mid \mathfrak{h} / \mathfrak{s}}\right|_{\mathrm{F}}$. By loc. cit., Lemma 44, there exists $\varepsilon_{0}>0$ such that $X \mapsto \eta(X)^{-2 \varepsilon_{0}}$ is locally integrable on $\mathfrak{s}$. To obtain the statement, it is sufficient to prove that:
for each $\gamma_{0} \in S_{\sigma}$, there exists a compact neighborhood $U_{0}$ of 1 such that
the integral $\int_{U_{0}}\left|\Delta_{\sigma}\left(x_{m} \gamma_{0} \gamma\right)\right|_{\mathrm{F}}^{-\varepsilon_{0}} d \gamma$ converges.
If $x_{m} \gamma_{0}$ is $\sigma$-regular, there is a compact neighborhood $U_{0}$ of 1 in $S_{\sigma}$ such that $\left|\Delta_{\sigma}\left(x_{m} \gamma_{0} \gamma\right)\right|_{\mathrm{F}}=\left|\Delta_{\sigma}\left(x_{m} \gamma_{0}\right)\right|_{\mathrm{F}} \neq 0$ for all $\gamma \in U_{0}$. Hence (2.34) is clear.

Let us now assume that $x_{m} \gamma_{0}$ is not $\sigma$-regular. We choose an extension $\mathrm{F}^{\prime}$ of E such that $\underline{\tilde{S}}$ splits over $\mathrm{F}^{\prime}$ and $p\left(x_{m}\right) \in \tilde{S}_{\sigma}\left(\mathrm{F}^{\prime}\right)$. We use notation of (1.27). Let $\Phi_{0}$ be the set of root $\alpha$ in $\Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)$ such that $\underline{p}\left(x_{m} \gamma_{0}\right)^{\alpha}=1$. We set

$$
\nu(\gamma)=\prod_{\alpha \in \Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)-\Phi_{0}}\left|1-\underline{p}\left(x_{m} \gamma_{0}\right)^{\alpha} \gamma^{-2 \alpha}\right|_{F^{\prime}}^{2}
$$

We have $\Delta_{\sigma}\left(x_{m} \gamma_{0} \gamma\right)=D_{G^{\prime}}\left(\underline{p}\left(x_{m} \gamma_{0}\right) \gamma^{-2}\right)=\operatorname{det}\left(1-\operatorname{Ad}\left(\underline{p}\left(x_{m} \gamma_{0}\right) \gamma^{-2}\right)\right)_{\mid \mathfrak{g} / \mathfrak{s}}$ and each root of $\Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)$ has multiplicity 2 . Hence, we obtain

$$
\left|\Delta_{\sigma}\left(x_{m} \gamma_{0} \gamma\right)\right|_{F^{\prime}}=\nu(\gamma) \prod_{\alpha \in \Phi_{0}}\left|1-\gamma^{-2 \alpha}\right|_{F^{\prime}}^{2}
$$

We choose a compact neighborhood $W$ of 1 in $S_{\sigma}$ such that $\nu(\gamma)=\nu(1) \neq 0$ for $\gamma \in W$. Let $\beta=\sup _{\gamma \in W} \prod_{\alpha \in \Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)-\Phi_{0}}\left|1-\gamma^{-2 \alpha}\right|_{F^{\prime}}^{2}$. Then, for $\gamma \in W$, we have

$$
\beta\left|\Delta_{\sigma}\left(x_{m} \gamma_{0} \gamma\right)\right|_{F^{\prime}}=\beta \nu(1) \prod_{\alpha \in \Phi_{0}}\left|1-\gamma^{-2 \alpha}\right|_{F^{\prime}}^{2} \geqslant \nu(1)\left|\Delta_{\sigma}(\gamma)\right|_{F^{\prime}}
$$

Consider the exponential map. There exist two open neighborhoods $\omega$ and $U$ of 0 in $\mathfrak{s}$ and 1 in $S_{\sigma}$ respectively, such that the map $X \mapsto \exp (\tau X)$ is well-defined on $\omega$ and is an isomorphism and an homeomorphism onto $U$. For $X \in \omega$, we have:

$$
\frac{\left|\Delta_{\sigma}(\exp (\tau X))\right|_{\mathrm{F}^{\prime}}^{1 / 2}}{\eta(X)}=\prod_{\alpha \in \Phi\left(S_{\sigma}^{\prime}, \mathfrak{g}^{\prime}\right)} \frac{\left|1-e^{2 \tau \alpha(X)}\right|_{\mathrm{F}^{\prime}}}{|\alpha(X)|_{\mathrm{F}^{\prime}}} .
$$

We can choose a compact neighborhood $\omega_{0} \subset \omega$ of 0 in $\mathfrak{s}$ such that the above product is a positive constant $c$ and $U_{0}:=\exp \left(\tau \omega_{0}\right)$ is contained in $W$. Then

$$
\int_{U_{0}}\left|\Delta_{\sigma}\left(x_{m} \gamma_{0} \gamma\right)\right|_{\mathrm{F}}^{-\varepsilon_{0}} d \gamma \leqslant\left(\frac{\nu(1)}{\beta}\right)^{-\varepsilon_{0}} \int_{U_{0}}\left|\Delta_{\sigma}(\gamma)\right|_{\mathrm{F}}^{-\varepsilon_{0}} d \gamma=\left(\frac{\nu(1)}{\beta}\right)^{-\varepsilon_{0}} c \int_{\omega_{0}} \eta(X)^{-2 \varepsilon_{0}} d X .
$$

The right hand side of this inequality is finite by our choice of $\varepsilon_{0}$. The assertion (2.34) follows.

To show 2., let us pick $\varepsilon_{0}>0$ as in 1. We set $I_{p}=\left.\left.\int_{S_{\sigma}(\varepsilon, T) \cap B}|\log | \Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}} ^{-1}\right|^{p} d \gamma$. If $p$ is a positive integer, then there is positive constant $C^{\prime}$ such that $|\log y|^{p} \leqslant C^{\prime} y^{\varepsilon_{0} / 2}$ for all $y \geqslant 1$. Since $\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{-1} \geqslant e^{\varepsilon\|T\|} \geqslant 1$ for all $\gamma \in S_{\sigma}(\varepsilon, T)$, we get:

$$
I_{p} \leqslant C^{\prime} \int_{S_{\sigma}(\varepsilon, T) \cap B}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{-\varepsilon_{0} / 2} d \gamma \leqslant C^{\prime} e^{-\frac{\varepsilon \varepsilon_{0}\|T\|}{2}} \int_{B}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{-\varepsilon_{0}} d \gamma
$$

If $p=0$, then, by definition of $S_{\sigma}(\varepsilon, T)$, one has:

$$
I_{0}=\int_{S_{\sigma}(\varepsilon, T) \cap B}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{-\varepsilon_{0}}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{\varepsilon_{0}} d \gamma \leqslant e^{-\varepsilon \varepsilon_{0}\|T\|} \int_{B}\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{-\varepsilon_{0}} d \gamma
$$

In the two cases, the result follows from 1.
2.7 Lemma. Let $\varepsilon_{0}>0$ as in Lemma 2.6. Given $\varepsilon>0$, we can choose a constant $c>0$ such that, for any $T \in a_{0, \mathrm{~F}}$, one has:

$$
\int_{S_{\sigma}(\varepsilon, T)}\left(\left|K^{T}\left(x_{m}, \gamma, f\right)\right|+\left|J^{T}\left(x_{m}, \gamma, f\right)\right|\right) d \gamma \leqslant c e^{-\frac{\varepsilon \varepsilon_{\|}\|T\|}{4}}
$$

Proof. We recall that:

$$
\begin{aligned}
& K^{T}\left(x_{m}, \gamma, f\right)=\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|^{1 / 2} \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} f_{1}\left(y_{1}^{-1} x_{m} \gamma y_{2}\right) \\
& \times f_{2}\left(x_{1}^{-1} x_{m} \gamma x_{2}\right) u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) d\left(x_{1}, x_{2}\right) \\
& d\left(y_{1}, y_{2}\right)
\end{aligned},
$$

where

$$
u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)=\int_{A_{H} \backslash A_{M}} u\left(y_{1}^{-1} a x_{1}, T\right) u\left(y_{2}^{-1} a x_{2}, T\right) d a .
$$

We first establish an estimate of $u_{M}$. Let $x, y \in H$ and $a \in A_{M}$. According to (1.11) applied to $H$, we can write $y^{-1} a x=k_{1} a_{0} k_{2}$ with $k_{1}, k_{2} \in K$ and $a_{0} \in A_{0}$. By definition of the norm, there is a positive constant $C_{0}$ such that:

$$
\log \left\|y^{-1} a x\right\| \leqslant C_{0}\left(\left\|h_{A_{0}}\left(a_{0}\right)\right\|+1\right)
$$

If $u\left(y^{-1} a x\right) \neq 0$, then, by definition of $u(\cdot, T)(c f .(2.7))$, the projection of $h_{A_{0}}\left(a_{0}\right)$ in $a_{H} \backslash a_{M}$ belongs to the convex hull in $a_{H} \backslash a_{M}$ of the $W\left(H, A_{0}\right)$-translates of $T$. Thus, there is a constant $C_{1}>0$ such that:

$$
\begin{equation*}
\inf _{z \in A_{H}} \log \left\|y^{-1} z a x\right\| \leqslant C_{1}(\|T\|+1) \tag{2.35}
\end{equation*}
$$

We assume that $\|T\| \geqslant 1$. Taking $C_{2}=\max \left(2 C_{1}, 1\right)$ and using the property (1.17) of the norm, we obtain:

$$
\begin{equation*}
\inf _{z \in A_{H}} \log \|z a\| \leqslant C_{2}(\|T\|+\log \|x\|+\log \|y\|) \tag{2.36}
\end{equation*}
$$

Applying this inequality to $\left(x_{1}, y_{1}\right)$ and $\left(x_{2}, y_{2}\right)$ such that $u\left(y_{1}^{-1} a x_{1}, T\right) u\left(y_{2}^{-1} a x_{2}, T\right) \neq$ 0 , we get:

$$
\inf _{z \in A_{H}} \log \|z a\| \leqslant C_{2}\left(\|T\|+\log \left\|x_{1}\right\|+\log \left\|y_{1}\right\|+\log \left\|x_{2}\right\|+\log \left\|y_{2}\right\|\right)
$$

As $\|x\| \leqslant\left\|x_{m}\right\|\left\|x_{m}^{-1} x\right\|$ and $1 \leqslant\|T\|$, and taking the integral over $a \in A_{H} \backslash A_{M}$ on the above inequality, we deduce the following inequality:

$$
\begin{align*}
u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) \leqslant & \left(\|T\|+\log \left\|x_{m}^{-1} x_{1}\right\|+\log \left\|x_{m}^{-1} y_{1}\right\|\right.  \tag{2.37}\\
& \left.+\log \left\|x_{2}\right\|+\log \left\|y_{2}\right\|\right), \quad x_{1}, y_{1}, x_{2}, y_{2} \in H
\end{align*}
$$

The function $u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ is invariant by the diagonal (left) action of $A_{M}$ on $\left(x_{1}, x_{2}\right)$ and $\left(y_{1}, y_{2}\right)$. As $x_{m}$ commutes with $A_{S}=A_{M}$ (cf. Lemma 1.1), we can replace $\log \left\|x_{m}^{-1} x_{1}\right\|+\log \left\|x_{2}\right\|$ and $\log \left\|x_{m}^{-1} y_{1}\right\|+\log \left\|y_{2}\right\|$ by $\inf _{a \in A_{M}} \log \left\|\left(a x_{m}^{-1} x_{1}, a x_{2}\right)\right\|$ and $\inf _{a \in A_{M}} \log \left\|\left(a x_{m}^{-1} y_{1}, a y_{2}\right)\right\|$ respectively. By assumption, the quotient $A_{M} \backslash S$ is compact. Then, using (1.21), one has:

$$
\inf _{a \in A_{M}}\left\|\left(a x_{m}^{-1} x, a x^{\prime}\right)\right\| \approx \inf _{s \in S}\left\|\left(s x_{m}^{-1} x, s x^{\prime}\right)\right\|, \quad x, x^{\prime} \in H
$$

Therefore, as $\|T\| \geqslant 1$, the inequality (2.37) gives

$$
\begin{array}{r}
u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) \leqslant\|T\|+\log \inf _{s \in S}\left\|\left(s x_{m}^{-1} x_{1}, s x_{2}\right)\right\|+\log \inf _{s \in S}\left\|\left(s x_{m}^{-1} y_{1}, s y_{2}\right)\right\|, \\
x_{1}, y_{1}, x_{2}, y_{2} \in H
\end{array}
$$

In other words, this means that there are a positive constant $C_{3}$ and a positive integer $d$ such that, for all $x_{1}, y_{1}, x_{2}$ and $y_{2} \in H$, one has:

$$
u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) \leqslant C_{3}\left(\|T\|+\log \inf _{s \in S}\left\|\left(s x_{m}^{-1} x_{1}, s x_{2}\right)\right\|+\log \inf _{s \in S}\left\|\left(s x_{m}^{-1} y_{1}, s y_{2}\right)\right\|\right)^{d}
$$

Let $\Omega$ be a compact set containing the support of $f_{1}$ and $f_{2}$. By Lemma 2.5, there is a positive integer $k$ (independent of $\Omega$ ) and a positive constant $C_{\Omega}$ such that, if $x_{m} \gamma \in x_{m} S_{\sigma}$ is a $\sigma$-regular point with $f_{1}\left(y_{1}^{-1} x_{m} \gamma y_{2}\right) f_{2}\left(x_{1}^{-1} x_{m} \gamma x_{2}\right) \neq 0$ for some $x_{1}, x_{2}, y_{1}$ and $y_{2}$ in $H$, then

$$
u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) \leqslant C_{\Omega}\left(\|T\|+\log \left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|^{-k}\right)^{d}
$$

This inequality and the expression of $K^{T}\left(x_{m}, \gamma, f\right)$ thus give that:

$$
\begin{equation*}
\left|K^{T}\left(x_{m}, \gamma, f\right)\right| \leqslant C_{\Omega}\left(\|T\|+\log \left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|^{-k}\right)^{d}\left|\mathcal{M}\left(f_{1}\right)\left(x_{m} \gamma\right) \mathcal{M}\left(f_{2}\right)\left(x_{m} \gamma\right)\right|, \tag{2.38}
\end{equation*}
$$

where $\mathcal{M}\left(f_{j}\right)$ is the orbital integral of $f_{j}$ defined in (1.34). By Theorem 1.2, these orbital integrals are bounded by a positive constant $C_{4}$ on $\left(x_{m} S_{\sigma}\right) \cap G^{\sigma-r e g}$. Hence, we obtain

$$
\left|K^{T}\left(x_{m}, \gamma, f\right)\right| \leqslant C_{\Omega} C_{4}^{2}\left(\|T\|+\log \left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|^{-k}\right)^{d}
$$

Let $B$ be the set of $\gamma$ in $S_{\sigma}$ such that $K^{T}\left(x_{m}, \gamma, f\right) \neq 0$. Then $B$ is bounded by Theorem 1.2 and (2.38). Using Lemma 2.6, we can find a constant $C>0$ such that

$$
\begin{equation*}
\int_{S_{\sigma}(\varepsilon, T)}\left|K^{T}\left(x_{m}, \gamma, f\right)\right| d \gamma \leqslant C e^{-\frac{\varepsilon \varepsilon_{0}\|T\|}{4}} \tag{2.39}
\end{equation*}
$$

If $\|T\| \leqslant 1$, then (2.35) implies that, if $u\left(x^{-1} a y\right) \neq 0$, then

$$
\inf _{z \in A_{H}} \log \|z a\| \leqslant 2 C_{1}+\log \|x\|+\log \|y\|
$$

The same arguments used to get (2.37) thus imply that there is a positive constant $C_{1}^{\prime}$ such that:

$$
\begin{equation*}
u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) \leqslant\left(C_{1}^{\prime}+\log \left\|x_{m}^{-1} x_{1}\right\|+\log \left\|x_{m}^{-1} y_{1}\right\|+\log \left\|x_{2}\right\|+\log \left\|y_{2}\right\|\right) \tag{2.40}
\end{equation*}
$$

for $x_{1}, y_{1}, x_{2}$ and $y_{2}$ in $H$. Replacing $\|T\|$ by $C_{1}^{\prime}$ in the argument after (2.37), we deduce that $\int_{S_{\sigma}(\varepsilon, T)}\left|K^{T}\left(x_{m}, \gamma, f\right)\right| d \gamma$ is bounded. Hence, one obtains (2.39) for $\|T\| \leqslant 1$.

We will now establish a similar estimate when $K^{T}$ is replaced by $J^{T}$. For this, it is enough to prove that the weight function $v_{M}$ has an estimate like (2.37). We will see that this follows easily from the definition of $v_{M}$. Indeed, for $x_{1}, y_{1}, x_{2}$ and $y_{2}$ in $H$, one has by definition:

$$
v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right):=\int_{A_{H} \backslash A_{M}} \sigma_{M}\left(h_{M}(a), \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right) d a
$$

where $\sigma_{M}\left(\cdot, \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right)$ is a bounded function which vanishes in the complement of the convex hull $\mathcal{S}_{M}\left(\mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right)$ of the ( $H, M$ )-orthogonal set $\mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\left(\right.$ cf. (2.5)). As $\mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ is the set of points $Z_{P}=$ $\inf ^{P}\left(T_{P}+h_{P}\left(y_{1}\right)-h_{\bar{P}}\left(x_{1}\right), T_{P}+h_{P}\left(y_{2}\right)-h_{\bar{P}}\left(x_{2}\right)\right)$ for $P \in \mathcal{P}(M)$ (cf. (2.11)), if $\sigma_{M}\left(X, \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right) \neq 0$, then $\|X\| \leqslant\left\|Z_{P}\right\|$ for $P \in \mathcal{P}(M)$. By definition of $T_{P}$, one has $\left\|T_{P}\right\| \leqslant\|T\|$. Let us prove that, for any $P \in \mathcal{P}(M)$, one has:

$$
\begin{equation*}
\left\|h_{P}(x)\right\| \leqslant 1+\log \|x\|, \quad x \in H . \tag{2.41}
\end{equation*}
$$

Le us first compare $\|m\|$ and $\left\|h_{M}(m)\right\|$ for any $m \in M$. Let $M=K_{M} A_{0} K_{M}$ be the Cartan decomposition of $M$ where $K_{M}$ is a suitable compact subgroup of $M$. Then each $m \in M$ can be written $m=k a(m) k^{\prime}$, with $k, k^{\prime} \in K_{M}$ and $a(m) \in A_{0}$. As $K_{M}$ is compact, (1.21) gives the property $\|m\| \approx\|a(m)\|, m \in M$, and this property does not depend on our choice of $a(m)$. By (1.25), we have $\|a\| \approx e^{\left\|h_{A_{0}}(a)\right\|}, a \in A_{0}$.
Hence, there are a positive constant $C$ and a nonnegative integer $d$ such that $e^{\left\|h_{A_{0}}(a(m))\right\|} \leqslant C\|m\|^{d}, m \in M$. Applying (1.8) to ( $M, A_{0}$ ), one has, for any $a \in A_{0}$, that $h_{M}(a)$ is the orthogonal projection of $h_{A_{0}}(a)$ onto $a_{M}$. Thus $\left\|h_{M}(a)\right\| \leqslant\left\|h_{A_{0}}(a)\right\|$. As $h_{M}(m)=h_{M}(a(m))$ for any $m \in M$, we then obtain that there is a positive constant $C^{\prime}$ such that:

$$
\begin{equation*}
\left\|h_{M}(m)\right\| \leqslant\left\|h_{A_{0}}(a(m))\right\| \leqslant C^{\prime}(1+\log \|m\|), \quad m \in M \tag{2.42}
\end{equation*}
$$

By definition of $m_{P}$ and $h_{P}$ (cf. (1.13) and (1.14)), we have $h_{P}(x)=h_{M}\left(m_{P}(x)\right)$ for any $x \in H$. Moreover, according to (1.22), we have $\left\|m_{P}(x)\right\| \leqslant\|x\|, x \in H$. Thus our claim (2.41) follows from (2.42).

Therefore, there are a positive constant $C_{1}$ and a positive integer $d$ such that, if $\sigma_{M}\left(h_{M}(a), \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right) \neq 0$, then

$$
\left\|h_{M}(a)\right\| \leqslant\left\|Z_{P}\right\| \leqslant C_{1}\left(\|T\|+\log \left\|x_{1}\right\|+\log \left\|y_{1}\right\|+\log \left\|x_{2}\right\|+\log \left\|y_{2}\right\|\right)^{d} .
$$

As $\|x\| \leqslant\left\|x_{m}\right\|\left\|x_{m}^{-1} x\right\|$ for any $x \in H$, this gives the following estimate of $v_{M}$ analogous to (2.37) and (2.40):

$$
\begin{align*}
& \text { if }\|T\|>1 \text {, then } \\
& v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) \leqslant\|T\|+\log \left\|x_{m}^{-1} x_{1}\right\|+\log \left\|x_{m}^{-1} y_{1}\right\|+\log \left\|x_{2}\right\|+\log \left\|y_{2}\right\|, \\
& x_{1}, y_{1}, x_{2}, y_{2} \in H, \tag{2.43}
\end{align*}
$$

and
there is a positive constant $C_{2}^{\prime}$ such that, for any $\|T\| \leqslant 1$, one has:
$v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) \leqslant C_{2}^{\prime}+\log \left\|x_{m}^{-1} x_{1}\right\|+\log \left\|x_{m}^{-1} y_{1}\right\|+\log \left\|x_{2}\right\|+\log \left\|y_{2}\right\|$, $x_{1}, y_{1}, x_{2}, y_{2} \in H$.

Arguing exactly as we did above for $K^{T}$, we deduce that there is a positive constant $C^{\prime}$ such that:

$$
\int_{S_{\sigma}(\varepsilon, T)}\left|J^{T}\left(x_{m}, \gamma, f\right)\right| d \gamma \leqslant C^{\prime} e^{-\frac{\varepsilon \varepsilon_{0}\|T\|}{4}}
$$

This finishes the proof of the Lemma.
2.8 Lemma. Fix $\delta>0$. Then there exist positive numbers $C, \varepsilon_{1}$ and $\varepsilon_{2}$ such that, for all $T$ with $d(T) \geqslant \delta\|T\|$, and for all $x_{1}, y_{1}, x_{2}$ and $y_{2}$ in the set $H_{\varepsilon_{2}}:=\{x \in$ $\left.H ;\|x\| \leqslant e^{\varepsilon_{2}\|T\|}\right\}$, one has:

$$
\begin{equation*}
\left|u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)-v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right| \leqslant C e^{-\varepsilon_{1}\|T\|} \tag{2.45}
\end{equation*}
$$

Proof. If $\|T\|$ remains bounded then, by (2.37), (2.40), (2.43) and (2.44), the functions $u_{M}$ and $v_{M}$ are bounded and the result (2.45) is trivial. Thus we have only to prove the Lemma for $\|T\|$ sufficiently large and $d(T) \geqslant \delta\|T\|$.

By $\left[\operatorname{Ar} 3\right.$, equation (5.8)], we can choose $\varepsilon_{2}$ such that $d\left(\mathcal{Y}_{M}(x, y, T)\right)>0$ for all $x, y \in H_{\varepsilon_{2}}$. By the discussion of loc.cit., bottom of page 38 and top of page 39, there is a constant $C_{0}>0$ such that, for $T$ with $d(T) \geqslant \delta\|T\|$ and $\|T\|>C_{0}, x, y \in H_{\varepsilon_{2}}$ and $a \in A_{H} \backslash A_{M}$, one has:

$$
u\left(y^{-1} a x, T\right)=\sigma_{M}\left(h_{M}(a), \mathcal{Y}_{M}(x, y, T)\right)
$$

By Lemma 2.2, we have, for $X \in a_{M}$,

$$
\sigma_{M}\left(X, \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right)=\sigma_{M}\left(X, \mathcal{Y}_{M}\left(x_{1}, y_{1}, T\right)\right) \sigma_{M}\left(X, \mathcal{Y}_{M}\left(x_{2}, y_{2}, T\right)\right)
$$

Thus, one deduces that:

$$
\sigma_{M}\left(h_{M}(a), \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right)=u\left(y_{1}^{-1} a x_{1}, T\right) u\left(y_{2}^{-1} a x_{2}, T\right), \quad a \in A_{H} \backslash A_{M}
$$

Hence, for $T$ such that $d(T) \geqslant \delta\|T\| \geqslant \delta C_{0}$ and $x_{i}, y_{i}$ in $H_{\varepsilon_{2}}$, we have:

$$
u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)=v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)
$$

This finishes the proof of the Lemma.

Theorem 2.3 then follows from the corollary below.
2.9 Corollary. Fix $\delta>0$. There exist two positive numbers $\varepsilon$ and $c>0$ such that, for all $T$ with $d(T) \geqslant \delta\|T\|$, one has:

$$
\begin{equation*}
\int_{\gamma \in S_{\sigma}}\left|K^{T}\left(x_{m}, \gamma, f\right)-J^{T}\left(x_{m} \gamma, f\right)\right| d \gamma \leqslant c e^{-\varepsilon\|T\|} \tag{2.46}
\end{equation*}
$$

Proof. By Lemma 2.7, it is enough to prove that we can find positive numbers $\varepsilon, \varepsilon^{\prime}$ and $C_{0}$ such that:

$$
\begin{equation*}
\int_{\gamma \in S_{\sigma}-S_{\sigma}(\varepsilon, T)}\left|K^{T}\left(x_{m}, \gamma, f\right)-J^{T}\left(x_{m}, \gamma, f\right)\right| d \gamma \leqslant C_{0} e^{-\varepsilon^{\prime}\|T\|} \tag{2.47}
\end{equation*}
$$

where $S_{\sigma}(\varepsilon, T)$ is defined in (2.33).
Let $\varepsilon>0$. Let $\Omega$ be a compact subset of $G$ which contains the supports of $f_{1}$ and $f_{2}$. We will estimate $\left|u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)-v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right|$ for $x_{1}, x_{2}, y_{1}$ and $y_{2}$ in $H$ satisfying $x_{1}^{-1} x_{m} \gamma x_{2} \in \Omega$ and $y_{1}^{-1} x_{m} \gamma y_{2} \in \Omega$ for some $\gamma \in S_{\sigma}-S_{\sigma}(\varepsilon, T)$ with $x_{m} \gamma \in G^{\sigma-r e g}$. For this, we will use the invariance of the functions $u_{M}$ and $v_{M}$ by the diagonal left action of $A_{M}$ on $\left(x_{1}, x_{2}\right)$ and $\left(y_{1}, y_{2}\right)$ respectively.

By Lemma 2.5, there are a positive integer $k$ and a positive constant $C_{\Omega}$ (depending only on $\Omega$ ) such that, for all $\gamma \in S_{\sigma}-S_{\sigma}(\varepsilon, T)$ with $x_{m} \gamma \in G^{\sigma-r e g}$ and for all $x_{i}, y_{i}$ in $H, i=1,2$, with $x_{1}^{-1} x_{m} \gamma x_{2}$ and $y_{1}^{-1} x_{m} \gamma y_{2}$ in $\Omega$, one has:

$$
\begin{equation*}
\inf _{s \in S}\left\|\left(s x_{m}^{-1} x_{1}, s x_{2}\right)\right\| \leqslant C_{\Omega} \Delta_{\sigma}\left(x_{m} \gamma\right)^{-k} \leqslant C_{\Omega} e^{k \varepsilon\|T\|} \tag{2.48}
\end{equation*}
$$

and

$$
\inf _{s \in S}\left\|\left(s x_{m}^{-1} y_{1}, s y_{2}\right)\right\| \leqslant C_{\Omega} \Delta_{\sigma}\left(x_{m} \gamma\right)^{-k} \leqslant C_{\Omega} e^{k \varepsilon\|T\|}
$$

As $A_{M} \backslash S$ is compact, we deduce from (1.21) and (2.48) that there is a constant $C_{\Omega}^{\prime}>0$ such that:

$$
\inf _{a \in A_{M}}\left\|\left(a x_{m}^{-1} x_{1}, a x_{2}\right)\right\| \leqslant C_{\Omega}^{\prime} e^{k \varepsilon\|T\|}
$$

Thus, for $\eta>0$, there exists $a_{0} \in A_{M}$ such that:

$$
\begin{equation*}
\left\|a_{0} x_{m}^{-1} x_{1}\right\|\left\|a_{0} x_{2}\right\| \leqslant C_{\Omega} e^{k \varepsilon\|T\|}+\eta . \tag{2.49}
\end{equation*}
$$

Since $A_{M}=A_{S}$, the point $a_{0}$ commutes with $x_{m}$ by (1.28) and we have $\left\|a_{0} x_{1}\right\| \leqslant$ $\left\|x_{m}\right\|\left\|x_{m}^{-1} a_{0} x_{1}\right\|$.

If $\|T\|$ remains bounded, then $\left\|a_{0} x_{i}\right\|, i=1,2$, are bounded by a constant independent of $\|T\|$. By the same arguments, there exists $a_{1} \in A_{M}$ such that $\left\|a_{1} y_{i}\right\|$, $i=1,2$, are bounded by a constant independent of $\|T\|$. Using the invariance of $u_{M}$ and $v_{M}$ by the left action of $\operatorname{diag}\left(A_{M}\right)$ on $\left(x_{1}, x_{2}\right)$ and ( $y_{1}, y_{2}$ ) respectively and the estimates (2.37), (2.40), (2.43) and (2.44) for $u_{M}$ and $v_{M}$, we deduce that $\left|u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)-v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right|$ is bounded by a constant independent of $T$ and of $x_{i}, y_{i}, i=1,2$. Recall that, by Theorem 1.2, the constant

$$
C_{1}:=\int_{S_{\sigma}} \mathcal{M}\left(\left|f_{1}\right|\right)\left(x_{m} \gamma\right) \mathcal{M}\left(\left|f_{2}\right|\right)\left(x_{m} \gamma\right) d \gamma
$$

is finite. We deduce that $\int_{\gamma \in S_{\sigma}-S_{\sigma}(\varepsilon, T)}\left|K^{T}\left(x_{m}, \gamma, f\right)-J^{T}\left(x_{m}, \gamma, f\right)\right| d \gamma$ is bounded, hence we obtain (2.47).

We assume that $\|T\|$ is not bounded. Let $\varepsilon_{1}, \varepsilon_{2}$ and $C$ as in Lemma 2.8. Taking $\|T\|$ to be sufficiently large and $\varepsilon$ such that $k \varepsilon$ is smaller than the constant $\varepsilon_{2}$, we can assume by (2.49) that:

$$
\left\|a_{0} x_{i}\right\| \leqslant e^{\varepsilon_{2}\|T\|}, \quad i=1,2 .
$$

The same arguments are valid for $\left\|y_{i}\right\|, i=1,2$. Thus there is $a_{1} \in A_{M}$ such that:

$$
\left\|a_{1} y_{i}\right\| \leqslant e^{\varepsilon_{2}\|T\|}, \quad i=1,2 .
$$

Using Lemma 2.8 and the invariance of $u_{M}$ and $v_{M}$ by the left action of the diagonal of $A_{M}$ on $\left(x_{1}, x_{2}\right)$ and $\left(y_{1}, y_{2}\right)$ respectively, we deduce that, for all $T$ with $d(T) \geqslant$ $\delta\|T\|$, one has

$$
\left|u_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)-v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right| \leqslant C e^{-\varepsilon_{1}\|T\|}
$$

Hence, we obtain

$$
\int_{S-S_{\sigma}(\varepsilon, T)}\left|K^{T}\left(x_{m}, \gamma, f\right)-J^{T}\left(x_{m}, \gamma, T\right)\right| \leqslant C C_{1} e^{-\varepsilon_{1} \| T \mid}
$$

where $C_{1}:=\int_{S_{\sigma}} \mathcal{M}\left(\left|f_{1}\right|\right)\left(x_{m} \gamma\right) \mathcal{M}\left(\left|f_{2}\right|\right)\left(x_{m} \gamma\right) d \gamma$. This finishes the proof of the Corollary.

### 2.5 The function $J^{T}(f)$

The goal of this Section is to prove that $J^{T}(f)$ is of the form

$$
\begin{equation*}
\sum_{k=0}^{N} p_{k}(T, f) e^{\xi_{k}(T)} \tag{2.50}
\end{equation*}
$$

where $\xi_{0}=0, \xi_{1}, \ldots, \xi_{N}$ are distinct points in $i a_{0}^{*}$ and each $p_{k}(T, f)$ is a polynomial function of $T$. Moreover, the constant term $\tilde{J}(f):=p_{0}(0, f)$ is well-defined and is uniquely determined by $K^{T}(f)$. Except for one detail, our arguments and calculations are the same as those of [Ar3, Section 6]. We give the details of the proof for convenience of the reader.

Recall that $J^{T}(f)$ is a finite sum of the distributions

$$
\begin{aligned}
J^{T}\left(x_{m}, \gamma, f\right)=\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|_{\mathrm{F}}^{1 / 2} & \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} \\
& \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} f_{1}\left(x_{1}^{-1} x_{1}^{-1} x_{m} \gamma y_{2}\right) \\
& \left.x_{2}\right) v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right) d \overline{\left(x_{1}, x_{2}\right)} d \overline{\left(y_{1}, y_{2}\right)},
\end{aligned}
$$

where $M \in \mathcal{L}\left(A_{0}\right), S$ is a maximal torus of $M$ such that $A_{S}=A_{M}, x_{m} \in$ $\kappa_{S}$ and $v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right):=\int_{A_{H} \backslash A_{M}} \sigma_{M}\left(h_{M}(a), \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right) d a$ where $\mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ is defined in (2.11).

We first study the weight function $v_{M}$ as a function of $T$. We fix $M \in \mathcal{L}\left(A_{0}\right)$ and $x_{1}, y_{1}, x_{2}$ and $y_{2}$ in $H$.

Let $\mathscr{L}_{M}:=\left(a_{M, \mathrm{~F}}+a_{H}\right) / a_{H}$ and $\widetilde{\mathscr{L}_{M}}:=\left(\tilde{a}_{M, \mathrm{~F}}+a_{H}\right) / a_{H}$ be the projection in $a_{M} / a_{H}$ of the lattices $a_{M, \mathrm{~F}}$ and $\tilde{a}_{M, \mathrm{~F}}$ respectively. According to (1.10), one has:

$$
\begin{equation*}
\tilde{a}_{M, \mathrm{~F}} / \tilde{a}_{H, \mathrm{~F}}=\tilde{a}_{M, \mathrm{~F}} / \tilde{a}_{M, \mathrm{~F}} \cap a_{H} \simeq \widetilde{\mathscr{L}_{M}} . \tag{2.51}
\end{equation*}
$$

For $M=A_{0}$, we replace the subscript $A_{0}$ by 0 . We denote by $\mathscr{L}^{\vee}:=\operatorname{Hom}(\mathscr{L}, 2 \pi i \mathbb{Z})$ the dual lattice of a lattice $\mathscr{L}$.

Let $P \in \mathcal{P}(M)$. We introduce the following sublattice of $\mathscr{L}_{M}$. For $k \in \mathbb{N}$, we set

$$
\mu_{\alpha, k}:=k \log (q) \check{\alpha}, \alpha \in \Delta_{P},
$$

where $q$ is the order of the residual field of F , and

$$
\mathscr{L}_{M, k}:=\sum_{\alpha \in \Delta_{P}} \mathbb{Z} \mu_{\alpha, k} .
$$

Then $\mathscr{L}_{M, k}$ is a lattice in $a_{M}^{H} \simeq a_{M} / a_{H}$ independent of $P$ and, according to [Ar2, Section 4], one can find $k \in \mathbb{N}^{*}$ such that, for all $M \in \mathcal{L}\left(A_{0}\right)$, one has:

$$
\mathscr{L}_{M, k} \subset \widetilde{\mathscr{L}_{M}}
$$

The set of points $\sum_{\alpha \in \Delta_{P}} y_{\alpha} \mu_{\alpha, k}$ with $\left.\left.y_{\alpha} \in\right]-1,0\right]$ is a fundamental domain of $\mathscr{L}_{M, k}$ which we denote by $\mathcal{D}_{M, k}$.

For $X \in \mathscr{L}_{M} / \mathscr{L}_{M, k}$ and $Y \in a_{M} / a_{H}$, we denote by $\bar{X}_{P}(Y)$ the represen-
tative of $X$ in $\mathscr{L}_{M}$ such that $\bar{X}_{P}(Y)-Y \in \mathcal{D}_{M, k}$.
For $\lambda \in a_{M, \mathbb{C}}^{*}$, we set:

$$
\begin{equation*}
\theta_{P, k}(\lambda)=\operatorname{vol}\left(a_{M}^{H} / \mathscr{L}_{M, k}\right)^{-1} \prod_{\alpha \in \Delta_{P}}\left(1-e^{-\lambda\left(\mu_{\alpha, k}\right)}\right) . \tag{2.53}
\end{equation*}
$$

We fix $T \in a_{0, \mathrm{~F}}$. By definition of $\sigma_{M}$ (cf. (2.4)), the function $v_{M}$ depends only on the image of $T_{P}$ in $\mathscr{L}_{M}$. Hence we can assume that $T$ lies in the lattice $\mathscr{L}_{0}$. For $P \in \mathcal{P}(M)$, the map $T \mapsto T_{P}$ sends surjectively $\mathscr{L}_{0}$ onto the intersection of $\mathscr{L}_{M}$ with the closure $\overline{a_{P}^{+}}$of the chamber associated to $P$. Thus, we may restrict $T$ to lie in the intersection of $\mathscr{L}_{0}$ with suitable regular points in some positive chamber $a_{0}^{+}$of $a_{H} \backslash a_{0}$. Then the points $T_{P}$ range over a suitable regular points in $\mathscr{L}_{M} \cap a_{P}^{+}$.

We recall that $\mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ is the set of points $Z_{P}:=Z_{P}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ defined in (2.10). Thus, we can write:

$$
\begin{equation*}
Z_{P}=T_{P}+Z_{P}^{0} \text { with } Z_{P}^{0}:=\inf ^{P}\left(h_{P}\left(y_{1}\right)-h_{\bar{P}}\left(x_{1}\right), h_{P}\left(y_{2}\right)-h_{\bar{P}}\left(x_{2}\right)\right) . \tag{2.54}
\end{equation*}
$$

Notice that the points $Z_{P}^{0}$ do not necessarily belong to the lattice $\mathscr{L}_{M}$. It is the only difference with [Ar3, Section 6] in what follows.
2.10 Lemma. There are a positive integer $N$ independent of $M$ and polynomial functions $q_{\xi}(T)$ for $\xi \in\left(\frac{1}{N} \mathscr{L}_{0}^{\vee}\right) / \mathscr{L}_{0}^{\vee}$ (depending on $x_{1}, y_{1}, x_{2}$ and $y_{2}$ ), such that:

$$
v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)=\sum_{\xi \in\left(\frac{1}{N} \mathscr{L}_{0}^{\vee}\right) / \mathscr{L}_{0}^{\vee}} q_{\xi}(T) e^{\xi(T)}
$$

Moreover, the constant term $\tilde{v}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}\right):=q_{0}(0)$ of $v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ is given by:

$$
\tilde{v}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}\right)=\lim _{\Lambda \rightarrow 0}\left(\sum_{P \in \mathcal{P}(M)}\left|\mathscr{L}_{M} / \mathscr{L}_{M, k}\right|^{-1} \sum_{X \in \mathscr{L}_{M} \mid \mathscr{L}_{M, k}} e^{\left\langle\Lambda, \bar{X}_{P}\left(Z_{P}^{0}\right)\right\rangle} \theta_{P, k}(\Lambda)^{-1}\right) .
$$

Proof. The kernel of the surjective map $h_{M}: A_{H} \backslash A_{M} \rightarrow \tilde{a}_{M, \mathrm{~F}} / \tilde{a}_{H, \mathrm{~F}}$ is a compact group which has volume 1 by our convention of choice of measure. Thus, using (2.51), we can write

$$
v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)=\sum_{X \in \widetilde{\mathscr{L}}_{M}} \sigma_{M}\left(X, \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right)
$$

For our study, it is convenient to take a sum over $\mathscr{L}_{M}$. The finite quotient $\widetilde{\mathscr{L}}_{M}{ }^{\vee} / \mathscr{L}_{M}^{\vee}$ can be identified with the character group of $\mathscr{L}_{M} / \widetilde{\mathscr{L}}_{M}$ under the pairing

$$
(\nu, X) \in \widetilde{\mathscr{L}}_{M}{ }^{v} / \mathscr{L}_{M}^{\vee} \times \mathscr{L}_{M} / \widetilde{\mathscr{L}_{M}} \mapsto e^{\nu(X)}
$$

Hence, by inversion formula on finite abelian groups, we obtain:

$$
v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)=\left|\mathscr{L}_{M} / \widetilde{\mathscr{L}_{M}}\right|^{-1} \sum_{\nu \in \widetilde{\mathscr{L}_{M}^{v}} \mid \mathscr{L}_{M}^{v}} \sum_{X \in \mathscr{L}_{M}} \sigma_{M}\left(X, \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right) e^{\nu(X)}
$$

Coming back to the definition of $\sigma_{M}$ (cf. (2.4)), we fix a small point $\Lambda \in\left(a_{M} / a_{H}\right)_{\mathbb{C}}^{*}$ whose real part $\Lambda_{R}$ is in general position. One then has:

$$
\begin{aligned}
\sigma_{M}\left(X, \mathcal{Y}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)\right) & =\sum_{P \in \mathcal{P}(M)}(-1)^{\left|\Delta_{P}^{\Lambda}\right|} \varphi_{P}^{\Lambda}\left(X-Z_{P}\right) \\
& =\lim _{\Lambda \rightarrow 0} \sum_{P \in \mathcal{P}(M)}(-1)^{\left|\Delta_{P}^{\Lambda}\right|} \varphi_{P}^{\Lambda}\left(X-Z_{P}\right) e^{\Lambda(X)} .
\end{aligned}
$$

By definition of $\varphi_{P}^{\Lambda}$, the function $X \mapsto e^{\Lambda(X)}$ is rapidly decreasing on the support of $X \mapsto \varphi_{P}^{\Lambda}\left(X-Z_{P}\right)$. Hence the product of these two functions is summable over $X \in \mathscr{L}_{M}$. Therefore, we can write:

$$
\begin{equation*}
v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)=\sum_{\nu \in \widetilde{\mathscr{L}_{M}} \mid \mathscr{L}_{M}^{v}} \lim _{\Lambda \rightarrow 0} \sum_{P \in \mathcal{P}(M)} F_{P}^{T}(\Lambda) \tag{2.55}
\end{equation*}
$$

where

$$
F_{P}^{T}(\Lambda):=\left|\mathscr{L}_{M} / \widetilde{\mathscr{L}_{M}}\right|^{-1} \sum_{X \in \mathscr{L}_{M}}(-1)^{\left|\Delta_{P}^{\Lambda}\right|} \varphi_{P}^{\Lambda}\left(X-Z_{P}\right) e^{(\Lambda+\nu)(X)} .
$$

The above discussion implies that:

$$
\begin{equation*}
\text { the map } \Lambda \mapsto \sum_{P \in \mathcal{P}(M)} F_{P}^{T}(\Lambda) \text { is analytic at } \Lambda=0 \tag{2.56}
\end{equation*}
$$

We fix $P \in \mathcal{P}(M)$. We want to express $F_{P}^{T}(\Lambda)$ in terms of a product of geometric series. For this, we write

$$
\begin{align*}
& F_{P}^{T}(\Lambda):=\left|\mathscr{L}_{M} / \widetilde{\mathscr{L}_{M}}\right|^{-1} \sum_{X \in \mathscr{L}_{M} \mid \mathscr{L}_{M, k}} \sum_{X^{\prime} \in \mathscr{L}_{M, k}}(-1)^{\left|\Delta_{P}^{\Lambda}\right|} \varphi_{P}^{\Lambda}\left(X+X^{\prime}-Z_{P}\right)  \tag{2.57}\\
& \times e^{(\Lambda+\nu)\left(X+X^{\prime}\right)} .
\end{align*}
$$

Let $X \in \mathscr{L}_{M} / \mathscr{L}_{M, k}$. Recall that $\bar{X}_{P}(Y)$ is the representative of $X$ in $\mathscr{L}_{M}$ such that $\bar{X}_{P}(Y)-Y \in \mathcal{D}_{M, k}$. We set

$$
\bar{X}_{P}^{\Lambda}(Y):=\bar{X}_{P}(Y)+\sum_{\alpha \in \Delta_{P}^{\Lambda}} \mu_{\alpha, k}
$$

Thus $\bar{X}_{P}^{\Lambda}(Y)$ is also a representative of $X$ in $\mathscr{L}_{M}$. Taking $Y:=Z_{P}$, we can set

$$
\varphi_{P}^{\Lambda}\left(X+X^{\prime}-Z_{P}\right)=\varphi_{P}^{\Lambda}\left(\bar{X}_{P}^{\Lambda}\left(Z_{P}\right)+X^{\prime}-Z_{P}\right)
$$

in (2.57). The set of points $X^{\prime} \in \mathscr{L}_{M, k}$ such that this characteristic function equals to 1 is exactly the set

$$
\left\{\sum_{\alpha \in \Delta_{P}^{\Lambda}} n_{\alpha} \mu_{\alpha, k}-\sum_{\alpha \in \Delta_{P}-\Delta_{P}^{\Lambda}} n_{\alpha} \mu_{\alpha, k} ; n_{\alpha} \in \mathbb{N}\right\} .
$$

Therefore, a simple calculation as in [Ar3, top of p. 45] gives

$$
\begin{align*}
& (-1)^{\left|\Delta_{P}^{\Lambda}\right|} \sum_{X^{\prime} \in \mathscr{L}_{M, k}} \varphi_{P}^{\Lambda}\left(X+X^{\prime}-Z_{P}\right) e^{(\Lambda+\nu)\left(X+X^{\prime}\right)} \\
= & e^{(\Lambda+\nu)\left(\bar{X}_{P}\left(Z_{P}\right)\right)} \prod_{\alpha \in \Delta_{P}}\left(1-e^{-(\Lambda+\nu)\left(\mu_{\alpha, k}\right)}\right)^{-1} . \tag{2.58}
\end{align*}
$$

We have fixed the Haar measure on $a_{M}^{H} \simeq a_{M} / a_{G}$ with the property that the quotient of $a_{M} / a_{H}$ by the lattice $\widetilde{\mathscr{L}_{M}}$ has volume 1 . Thus we have

$$
\left|\mathscr{L}_{M} / \widetilde{\mathscr{L}}_{M}\right|^{-1} \prod_{\alpha \in \Delta_{P}}\left(1-e^{-(\Lambda+\nu)\left(\mu_{\alpha, k}\right)}\right)^{-1}=\left|\mathscr{L}_{M} / \mathscr{L}_{M, k}\right|^{-1} \theta_{P, k}(\Lambda+\nu)^{-1}
$$

By the above equality, (2.57) and (2.58), we obtain:

$$
\begin{equation*}
F_{P}^{T}(\Lambda)=\left|\mathscr{L}_{M} / \mathscr{L}_{M, k}\right|^{-1} \sum_{X \in \mathscr{L}_{M} / \mathscr{L}_{M, k}} e^{<\Lambda+\nu, \bar{X}_{P}\left(Z_{P}\right)>} \theta_{P, k}(\Lambda+\nu)^{-1} \tag{2.59}
\end{equation*}
$$

Let $X \in \mathscr{L}_{M} / \mathscr{L}_{M, k}$. We recall that $T_{P}$ belongs to $\mathscr{L}_{M}$ for $P \in \mathcal{P}(M)$ and $Z_{P}=T_{P}+Z_{P}^{0}$ (cf. (2.54)). By definition (cf. (2.52)), the point $\bar{X}_{P}\left(Z_{P}\right)$ is the unique representative of $X$ in $\mathcal{L}_{M}$ such that $\bar{X}_{P}\left(Z_{P}\right)-T_{P}-Z_{P}^{0} \in \mathcal{D}_{M, k}$ and ${\overline{\left(X-T_{P}\right.}}_{P}\left(Z_{P}^{0}\right)$ is the unique representative of $X-T_{P}$ in $\mathscr{L}_{M}$ such that $\overline{\left(X-T_{P}\right)_{P}}\left(Z_{P}^{0}\right)-Z_{P}^{0} \in \mathcal{D}_{M, k}$. Hence we deduce that:

$$
\begin{equation*}
\bar{X}_{P}\left(Z_{P}\right)={\overline{\left(X-T_{P}\right)}}_{P}\left(Z_{P}^{0}\right)+T_{P} \tag{2.60}
\end{equation*}
$$

Replacing $X$ by $X-T_{P}$ in (2.59), we obtain:

$$
\begin{equation*}
F_{P}(\Lambda)^{T}=\left|\mathscr{L}_{M} / \mathscr{L}_{M, k}\right|^{-1} \sum_{X \in \mathscr{L}_{M} / \mathscr{L}_{M, k}} e^{<\Lambda+\nu, T_{P}+\bar{X}_{P}\left(Z_{P}^{0}\right)>} \theta_{P, k}(\Lambda+\nu)^{-1} \tag{2.61}
\end{equation*}
$$

where $\bar{X}_{P}\left(Z_{P}^{0}\right)$ is independent of $T$. Thus, by (2.55), we have established that $v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ is equal to:

$$
\begin{align*}
\sum_{\nu \in \widetilde{\mathscr{L}}_{M}^{\vee} / \mathscr{L}_{M}^{\vee}} \lim _{\Lambda \rightarrow 0}\left(\sum_{P \in \mathcal{P}(M)}\left|\mathscr{L}_{M} / \mathscr{L}_{M, k}\right|^{-1} \sum_{X \in \mathscr{L}_{M} / \mathscr{L}_{M, k}}\right. & e^{<\Lambda+\nu, T_{P}+\bar{X}_{P}\left(Z_{P}^{0}\right)>}  \tag{2.62}\\
& \left.\times \theta_{P, k}(\Lambda+\nu)^{-1}\right)
\end{align*}
$$

Recall that the expression in the brackets is analytic at $\Lambda=0$ (cf. (2.56)). To analyze this expression as function of $T$, we argue as in [W1, p. 315]. We give the details for convenience of the reader. We replace $\Lambda$ by $z \Lambda$. The map $z \mapsto \theta_{P, k}(z \Lambda+\nu)^{-1}$ may have a pole at $z=0$. Let $r$ denotes the biggest order of this pole when $P$ runs $\mathcal{P}(M)$. Then, using Taylor expansions, one deduces that:

$$
\begin{aligned}
& \lim _{\Lambda \rightarrow 0}\left(\sum_{P \in \mathcal{P}(M)}\left|\mathscr{L}_{M} / \mathscr{L}_{M, k}\right|^{-1} \sum_{\substack{X \in \mathscr{L}_{M} / \mathscr{L}_{M, k}}} e^{<\Lambda+\nu, T_{P}+\bar{X}_{P}\left(Z_{P}^{0}\right)>} \theta_{P, k}(\Lambda+\nu)^{-1}\right) \\
= & \sum_{m=0}^{r} \sum_{P \in \mathcal{P}(M)} C_{m} \sum_{X \in \mathscr{L}_{M} / \mathscr{L}_{M, k}} \frac{\partial^{m}}{\partial z^{m}}\left(e^{<z \Lambda+\nu, T_{P}+\bar{X}_{P}\left(Z_{P}^{0}\right)>}\right)_{[z=0]} \\
& \times \frac{\partial^{r-m}}{\partial z^{r-m}}\left(z^{r} \theta_{P, k}(z \Lambda+\nu)^{-1}\right)_{[z=0]},
\end{aligned}
$$

where $C_{m}=\frac{1}{m!(r-m)!}\left|\mathscr{L}_{M} / \mathscr{L}_{M, k}\right|^{-1}$. But we have

$$
\frac{\partial^{m}}{\partial z^{m}}\left(e^{<z \Lambda+\nu, T_{P}+\bar{X}_{P}\left(Z_{P}^{0}\right)>}\right)_{[z=0]}=\left(<\Lambda, T_{P}+\bar{X}_{P}\left(Z_{P}^{0}\right)>\right)^{m} e^{<\nu, T_{P}+\bar{X}_{P}\left(Z_{P}^{0}\right)>}
$$

and $\frac{\partial^{r-m}}{\partial z^{r-m}}\left(z^{r} \theta_{P, k}(z \Lambda+\nu)^{-1}\right)_{[z=0]}$ is independent of $T_{P}$.
Therefore, we deduce that $v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)$ is a finite sum of functions

$$
q_{P, \nu}\left(T_{P}\right) e^{\nu\left(T_{P}\right)}, \quad \nu \in \widetilde{\mathscr{L}}_{M}^{\vee} / \mathscr{L}_{M}^{\vee}, P \in \mathcal{P}(M)
$$

where $q_{P, \nu}$ is a polynomial function on $a_{M}$.

Since $\mathscr{L}_{0}^{\vee} \subset \widetilde{\mathscr{L}}_{0}{ }^{\vee}$ are lattices of same rank, one can find a positive integer $N$ such that $N \widetilde{\mathscr{L}}_{0} \subset \mathscr{L}_{0}^{\vee}$. Therefore, by our choice of $T$ and the above expression, we can write:

$$
v_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}, T\right)=\sum_{\xi \in\left(\frac{1}{N} \mathscr{L}_{0}^{\vee}\right) / \mathscr{L}_{0}^{\vee}} q_{\xi}(T) e^{\xi(T)}
$$

where $q_{\xi}(T)$ is a polynomial function of $T$. This gives the first part of the Lemma.
Since the polynomials $q_{\xi}(T)$ are obviously uniquely determined, the constant term $\tilde{v}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}\right):=q_{0}(0)$ is well defined. To calculate it, we take the summand corresponding to $\nu=0$ in (2.62) and then set $T=0$. We obtain:

$$
\tilde{v}_{M}\left(x_{1}, y_{1}, x_{2}, y_{2}\right)=\lim _{\Lambda \rightarrow 0}\left(\sum_{P \in \mathcal{P}(M)}\left|\mathscr{L}_{M} / \mathscr{L}_{M, k}\right|^{-1} \sum_{X \in \mathscr{L}_{M} / \mathscr{L}_{M, k}} e^{\left\langle\Lambda, \bar{X}_{P}\left(Z_{P}^{0}\right)\right\rangle} \theta_{P, k}(\Lambda)^{-1}\right) .
$$

This finishes the proof of the Lemma.

We substitute the expression we have obtained for $v_{M}$ in Lemma 2.10 into the expression for $J^{T}\left(x_{m}, \gamma, f\right)$. Hence we obtain the following similar decomposition for $J^{T}(f)$.
2.11 Corollary. There is a decomposition

$$
J^{T}(f)=\sum_{\xi \in\left(\frac{1}{N} \mathscr{L}_{0}^{\vee}\right) / \mathscr{L}_{0}^{\vee}} p_{\xi}(T, f) e^{\xi(T)}, \quad T \in \mathscr{L}_{0} \cap a_{0}^{+},
$$

where $N$ is positive integer and each $p_{\xi}(T, f)$ is a polynomial function of $T$. Moreover, the constant term $\tilde{J}(f):=p_{0}(0, f)$ of $J^{T}(f)$ is given by:

$$
\tilde{J}(f):=\sum_{M \in \mathcal{L}\left(A_{0}\right)} c_{M} \sum_{S \in \mathcal{T}_{M}} \sum_{x_{m} \in \kappa_{S}} c_{S, x_{m}} \int_{S_{\sigma}} \tilde{J}\left(x_{m}, \gamma, f\right) d \gamma
$$

where

$$
\tilde{J}\left(x_{m}, \gamma, f\right)=\left|\Delta_{\sigma}\left(x_{m} \gamma\right)\right|^{1 / 2} \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} \int_{\operatorname{diag}\left(A_{M}\right) \backslash H \times H} f_{1}\left(y_{1}^{-1} x_{m} \gamma y_{2}\right) f_{2}\left(x_{1}^{-1} x_{m} \gamma x_{2}\right)
$$

## A Appendix. Spherical character of a supercuspidal representation as weighted orbital integral

Let $(\pi, V)$ be a unitary irreducible admissible representation of $G$. We say that $\pi$ is $H$-distinguished if the space $V^{* H}=\operatorname{Hom}_{H}(\pi, \mathbb{C})$ of $H$-invariant linear forms on $V$ is nonzero. In that case, a distribution $m_{\xi, \xi^{\prime}}$, called spherical character, can be associated to two $H$-invariant linear forms $\xi, \xi^{\prime}$ on $V$ (cf. definition below). By [Ha,

Theorem 1], spherical characters are locally integrable functions on $G$, which are smooth on the set of $\sigma$-regular points of $G$.

From now, we assume that $A_{H}=\{1\}$. We fix a $H$-distinguished supercuspidal representation $(\tau, V)$ of $G$. We denote by $d(\tau)$ its formal degree.

The aim of this appendix is to deduce from our main results, the value $m_{\xi, \xi^{\prime}}(g)$, when $g \in G$ is $\sigma$-regular and $\xi, \xi^{\prime} \in V^{* H}$, in terms of weighted orbital integrals of a matrix coefficient of $\tau$ (cf. Theorem A.2). This result is analogous to that of J. Arthur in the group case (see [Ar2]). Notice that this result of J. Arthur can be deduced from his local trace formula given in [Ar3], which was obtained later.

Let $(\cdot, \cdot)$ be a $G$-invariant hermitian inner product on $V$. Since $\tau$ is unitary, it induces an isomorphism $\iota: v \mapsto(\cdot, v)$ from the conjugate complex vector space $\bar{V}$ of $V$ and the smooth dual $\dot{V}$ of $V$, which intertwines the complex conjugate of $\tau$ and its contragredient $\check{\tau}$. If $\xi$ is a linear form on $V$, we define the linear form $\bar{\xi}$ on $\bar{V}$ by $\bar{\xi}(u):=\overline{\xi(u)}$.
For $\xi_{1}$ and $\xi_{2}$ two nonzero $H$-invariant linear forms on $V$, we associate the spherical character $m_{\xi_{1}, \xi_{2}}$ defined to be the distribution on $G$ given by:

$$
m_{\xi_{1}, \xi_{2}}(f):=\sum_{u \in \mathcal{B}} \xi_{1}(\tau(f) u) \overline{\xi_{2}(u)}
$$

where $\mathcal{B}$ is an orthonormal basis of $V$. Since $\tau(f)$ is of finite rank, this sum is finite. Moreover, this sum does not depend on the choice of $\mathcal{B}$. Indeed, let $\left(\tau^{*}, V^{*}\right)$ be the dual representation of $\tau$. For $f \in C_{c}^{\infty}(G)$, we set $\check{f}(g):=f\left(g^{-1}\right)$. By [R, Theorems III.3.4 and I.1.2], the linear form $\tau^{*}(\check{f}) \xi$ belongs to $\check{V}$. Hence we can write $\iota^{-1}\left(\tau^{*}(\check{f}) \xi\right)=\sum_{v \in \mathcal{B}}\left(\tau^{*}(\check{f}) \xi\right)(v) \cdot v$, where $(\lambda, v) \mapsto \lambda \cdot v$ is the action of $\mathbb{C}$ on $\bar{V}$. Therefore, we deduce easily that one has:

$$
\begin{equation*}
m_{\xi_{1}, \xi_{2}}(f)=\bar{\xi}_{2}\left(\iota^{-1}\left(\tau^{*}(\check{f}) \xi_{1}\right)\right) \tag{1.1}
\end{equation*}
$$

Since $\tau$ is a supercuspidal representation, we can define the $H \times H$-invariant pairing $\mathcal{L}$ on $V \times \bar{V}$ by:

$$
\mathcal{L}(u, v):=\int_{H}(\tau(h) u, v) d h
$$

According to [Z, Theorem 1.5],

$$
\begin{align*}
& \text { the map } v \mapsto \xi_{v}: u \mapsto \mathcal{L}(u, v) \text { is a surjective linear map from } \bar{V} \text { onto }  \tag{1.2}\\
& V^{* H} \text {. }
\end{align*}
$$

For $v, w \in V$, we denote by $c_{v, w}$ the corresponding matrix coefficient defined by $c_{v, w}(g):=(\tau(g) v, w), g \in G$.
A. 1 Lemma. Let $\xi_{1}, \xi_{2} \in V^{* H}$ and $v, w \in V$. Then we have:

$$
m_{\xi_{1}, \xi_{2}}\left(\check{c}_{v, w}\right)=d(\tau)^{-1} \xi_{1}(v) \overline{\xi_{2}(w)}
$$

Proof. By (1.2), there exist $v_{1}$ and $v_{2}$ in $V$ such that $\xi_{j}=\xi_{v_{j}}$ for $j=1,2$. By definition of the spherical character, for $f \in C_{c}^{\infty}(G)$ and $\mathcal{B}$ an orthonormal basis of $V$, one has:

$$
\begin{aligned}
m_{\xi_{1}, \xi_{2}}(f) & =\sum_{u \in \mathcal{B}} \int_{H}\left(\tau(h) \tau(f) u, v_{1}\right) d h \int_{H} \overline{\left(\tau(h) u, v_{2}\right)} d h \\
& =\sum_{u \in \mathcal{B}} \int_{H \times H}\left(u, \tau(\check{f}) \tau\left(h_{1}\right) v_{1}\right)\left(\tau\left(h_{2}\right) v_{2}, u\right) d h_{1} d h_{2} \\
& =\int_{H \times H}\left(\tau\left(h_{2}\right) v_{2}, \tau(\check{f}) \tau\left(h_{1}\right) v_{1}\right) d h_{1} d h_{2} .
\end{aligned}
$$

Hence we obtain

$$
\begin{equation*}
m_{\xi_{1}, \xi_{2}}(f)=\int_{H \times H} \int_{G} f(g)\left(\tau\left(h_{1} g h_{2}\right) v_{2}, v_{1}\right) d g d h_{1} d h_{2} \tag{1.3}
\end{equation*}
$$

Let $f(g):=\check{c}_{v, w}(g)=\overline{(\tau(g) w, v)}$. By the orthogonality relation of Schur, for $h_{1}, h_{2} \in$ $H$, one has:

$$
\int_{G}\left(\tau(g) \tau\left(h_{2}\right) v_{2}, \tau\left(h_{1}\right) v_{1}\right) \overline{(\tau(g) w, v)} d g=d(\tau)^{-1}\left(\tau\left(h_{2}\right) v_{2}, w\right)\left(v, \tau\left(h_{1}\right) v_{1}\right)
$$

Thus we deduce that:

$$
m_{\xi_{1}, \xi_{2}}(f)=d(\tau)^{-1} \xi_{w}\left(v_{2}\right) \xi_{v_{1}}(v)=d(\tau)^{-1} \xi_{1}(v) \overline{\xi_{2}(w)}
$$

For $M \in \mathcal{L}\left(A_{0}\right)$, we define the weight function $w_{M}$ on $H \times H$ by:

$$
w_{M}\left(y_{1}, y_{2}\right):=\tilde{v}_{M}\left(1, y_{1}, 1, y_{2}\right)
$$

where $\tilde{v}_{M}$ is defined in Lemma 2.10 and 1 is the neutral element of $H$. For $f \in C_{c}^{\infty}(G)$, we define the weighted orbital integral of $f$ by:

$$
\mathcal{W M}(f)(g):=\left|\Delta_{\sigma}(g)\right|^{1 / 2} \int_{H \times H} f\left(y_{1} g y_{2}\right) w_{M}\left(y_{1}, y_{2}\right) d y_{1} d y_{2}, \quad g \in G^{\sigma-r e g} \cap \tilde{M} .
$$

A. 2 Theorem. Let $M \in \mathcal{L}\left(A_{0}\right)$ and $S \in \mathcal{T}_{M}$. Let $x_{M} \in \kappa_{S}$ and $\gamma \in S_{\sigma}$ be such that $x_{m} \gamma$ is $\sigma$-regular. Then, for $v, w \in V$, we have:

$$
c_{M} c_{S, x_{m}} \mathcal{W} \mathcal{M}\left(c_{v, w}\right)\left(x_{m} \gamma\right)=m_{\xi_{w}, \xi_{v}}\left(x_{m} \gamma\right)
$$

Proof. Let $f_{1}$ be a matrix coefficient of $\tau$ and $f_{2} \in C_{c}^{\infty}(G)$. We set $f:=f_{1} \otimes f_{2}$. For $x \in G$, we define

$$
F(g):=\int_{G} f_{1}(x u) f_{2}(u g x) d u, \quad g \in G
$$

so that

$$
K_{f}(x, y)=\left[\rho\left(y x^{-1}\right) F\right](e) .
$$

If $\pi$ is a unitary irreducible admissible representation of $G$, one has:

$$
\begin{aligned}
\pi\left(\rho\left(y x^{-1}\right) F\right) & =\int_{G \times G} f_{1}(x u) f_{2}(u g y) \pi(g) d u d g \\
& =\int_{G \times G} f_{1}(x u) f_{2}\left(u_{2}\right) \pi\left(u^{-1} u_{2} y^{-1}\right) d u d u_{2} \\
& =\int_{G \times G} f_{1}\left(u_{1}^{-1}\right) f_{2}\left(u_{2}\right) \pi\left(u_{1} x u_{2} y^{-1}\right) d u_{1} d u_{2}=\pi\left(\check{f}_{1}\right) \pi(x) \pi\left(f_{2}\right) \pi\left(y^{-1}\right) .
\end{aligned}
$$

Since $\tau$ is supercuspidal and $f_{1}$ is a matrix coefficient of $\tau$, we deduce that $\pi\left(\rho\left(y x^{-1}\right) F\right)$ is equal to 0 if $\pi$ is not equivalent to $\tau$. Therefore, applying the Plancherel formula [W2, Theorem VIII.1.1] to $\left[\rho\left(y x^{-1}\right) F\right]$, we obtain:

$$
K_{f}(x, y)=d(\tau) \operatorname{tr}\left(\tau\left(\check{f}_{1}\right) \tau(x) \tau\left(f_{2}\right) \tau\left(y^{-1}\right)\right) .
$$

We identify $\check{V} \otimes V$ with a subspace of Hilbert-Schmidt operators on $V$. Taking an orthonormal basis $\mathcal{B}_{H S}(V)$ of $\dot{V} \otimes V$ for the scalar product $\left(S, S^{\prime}\right):=\operatorname{tr}\left(S S^{* *}\right)$, one obtains:

$$
\begin{aligned}
K_{f}(x, y) & =d(\tau) \operatorname{tr}\left(\tau\left(\check{f}_{1}\right) \tau(x) \tau\left(f_{2}\right) \tau(y)^{*}\right)=d(\tau)\left(\tau\left(\check{f}_{1}\right) \tau(x) \tau\left(f_{2}\right), \tau(y)\right) \\
& =d(\tau) \sum_{S \in \mathcal{B}_{H S}(V)}\left(\tau\left(\check{f}_{1}\right) \tau(x) \tau\left(f_{2}\right), S^{*}\right) \overline{\left(\tau(y), S^{*}\right)} \\
& =d(\tau) \sum_{S \in \mathcal{B}_{H S}(V)} \operatorname{tr}\left(\tau(x) \tau\left(f_{2}\right) S \tau\left(\check{f}_{1}\right)\right) \operatorname{tr} \overline{(\tau(y) S)}
\end{aligned}
$$

where the sums over $S$ are finite since $\tau\left(f_{2}\right)$ and $\tau\left(\check{f}_{1}\right)$ are of finite rank. Therefore, the truncated kernel $K^{T}(f)$ is equal to

$$
d(\tau) \sum_{S \in \mathcal{B}_{H S}(V)} P_{\tau}^{T}(\check{\tau} \otimes \tau(f) S) \overline{P_{\tau}^{T}(S)}
$$

where

$$
P_{\tau}^{T}(S)=\int_{H} \operatorname{tr}(\tau(h) S) u(h, T) d h, \quad S \in \check{V} \otimes V
$$

For $\check{v} \otimes v \in \check{V} \otimes V$, one has $\operatorname{tr}(\tau(h)(\check{v} \otimes v))=c_{\check{v}, v}(h)$. Since $c_{\check{v}, v}$ is compactly supported, the truncated local period $P_{\tau}^{T}(S)$ converges, when $\|T\|$ approaches infinity, to:

$$
P_{\tau}(S)=\int_{H} \operatorname{tr}(\tau(h) S) d h
$$

Therefore, we obtain

$$
\begin{equation*}
\lim _{\|T\| \rightarrow+\infty} K^{T}(f)=d(\tau) m_{P_{\tau}, P_{\tau}}(f) \tag{1.4}
\end{equation*}
$$

where $m_{P_{\tau}, P_{\tau}}$ is the spherical character of the representation $\check{\tau} \otimes \tau$ associated to the $H \times H$-invariant linear form $P_{\tau}$ on $\check{V} \otimes V$.

Recall that $\tilde{J}(f)$ is the constant term of $J^{T}(f)$. We deduce from Theorem 2.15 that

$$
\begin{equation*}
d(\tau) m_{P_{\tau}, P_{\tau}}(f)=\tilde{J}(f) \tag{1.5}
\end{equation*}
$$

We now express $m_{P_{\tau}, P_{\tau}}$ in terms of $H$-invariant linear forms on $V$. Let $V_{H}$ be the orthogonal of $V^{* H}$ in $V$. Since $\xi_{u}(v)=\overline{\xi_{v}(u)}$ for $u, v \in V$, the space $\overline{V_{H}}$ is the kernel of $v \mapsto \xi_{v}$. Let $W$ be a complementary subspace of $V_{H}$ in $V$. Then, the map $v \mapsto \xi_{v}$ is an isomorphism from $\bar{W}$ to $V^{* H}$ and $(u, v) \mapsto \xi_{v}(u)$ is a nondegenerate hermitian form on $W$. Let $\left(e_{1}, \ldots, e_{n}\right)$ be an orthogonal basis of $W$ for this hermitian form. We set $\xi_{i}:=\xi_{e_{i}}$ for $i=1, \ldots, n$. Thus we have $\xi_{i}\left(e_{i}\right) \neq 0$.
We identify $\bar{V}$ and $\check{V}$ by the isomorphism $\iota$. We claim that:

$$
\begin{equation*}
P_{\tau}=\sum_{i=1}^{n} \frac{1}{\xi_{i}\left(e_{i}\right)} \overline{\xi_{i}} \otimes \xi_{i} \tag{1.6}
\end{equation*}
$$

Indeed, we have $P_{\tau}(v \otimes u)=\xi_{v}(u)=\overline{\xi_{u}(v)}$. Hence, the two sides are equal to 0 on $\bar{V} \otimes V_{H}+\overline{V_{H}} \otimes V+\overline{V_{H}} \otimes V_{H}$ and take the same value $\xi_{k}\left(e_{l}\right)$ on $e_{k} \otimes e_{l}$ for $k, l \in\{1, \ldots n\}$. Hence, by definition of spherical characters, we deduce that:

$$
\begin{aligned}
m_{P_{\tau}, P_{\tau}}\left(f_{1} \otimes f_{2}\right) & =\sum_{u \otimes v \in o . b .(\bar{V} \otimes V)} P_{\tau}\left(\bar{\tau}\left(f_{1}\right) \otimes \tau\left(f_{2}\right)(u \otimes v)\right) \overline{P_{\tau}(u \otimes v)} \\
& =\sum_{u \otimes v \in o . b .(\bar{V} \otimes V)} \sum_{i, j=1}^{n} \frac{1}{\xi_{i}\left(e_{i}\right) \xi_{j}\left(e_{j}\right)} \overline{\xi_{i}}\left(\bar{\tau}\left(f_{1}\right) u\right) \xi_{i}\left(\tau\left(f_{2}\right) v\right) \overline{\overline{\xi_{j}}(u) \xi_{j}(v)},
\end{aligned}
$$

where o.b. $(\bar{V} \otimes V)$ is an orthonormal basis of $\bar{V} \otimes V$. By definition of $\bar{\xi}$ for $\xi \in V^{* H}$, one has $\bar{\xi}\left(\bar{\tau}\left(f_{1}\right) u\right)=\overline{\xi\left(\tau\left(\bar{f}_{1}\right)\right)}$. Therefore, we obtain:

$$
\begin{equation*}
m_{P_{\tau}, P_{\tau}}\left(f_{1} \otimes f_{2}\right)=\sum_{i, j=1}^{n} \frac{1}{\overline{\xi_{i}\left(e_{i}\right) \xi_{j}\left(e_{j}\right)} \overline{m_{\xi_{i}, \xi_{j}}\left(\overline{f_{1}}\right)} m_{\xi_{i}, \xi_{j}}\left(f_{2}\right) . . . . . . .} \tag{1.7}
\end{equation*}
$$

Let $v$ and $w$ be in $V$. Let $f_{1}:=c_{v, w}$ so that $\overline{f_{1}}=\check{c}_{v, w}$. If $v \in V_{H}$ or $w \in V_{H}$, it follows from Lemma A. 1 that $m_{\xi_{i}, \xi_{j}}\left(\bar{f}_{1}\right)=0$ for $i, j \in\{1, \ldots, n\}$. Hence $m_{P_{\tau}, P_{\tau}}\left(f_{1} \otimes f_{2}\right)=0$. Thus we deduce from (1.5) that:

$$
\begin{equation*}
\tilde{J}\left(c_{v, w} \otimes f_{2}\right)=0, \quad v \in V_{H} \text { or } w \in V_{H} . \tag{1.8}
\end{equation*}
$$

Let $k, l \in\{1, \ldots, n\}$. Let us take $f_{1}:=c_{e_{k}, e_{l}}$. Then $\overline{f_{1}}=\check{c}_{e_{l}, e_{k}}$ and, by Lemma A.1, one has $m_{\xi_{i}, \xi_{j}}\left(\bar{f}_{1}\right)=d(\tau)^{-1} \xi_{i}\left(e_{l}\right) \xi_{j}\left(e_{k}\right)$. Therefore, by (1.5) and (1.7), we obtain:

$$
\begin{equation*}
\tilde{J}\left(c_{e_{k}, e_{l}} \otimes f_{2}\right)=m_{\xi_{l}, \xi_{k}}\left(f_{2}\right) \tag{1.9}
\end{equation*}
$$

By sesquilinearity, one deduces from (1.8) and (1.9) that:

$$
\begin{equation*}
\tilde{J}\left(c_{v, w} \otimes f_{2}\right)=m_{\xi_{w}, \xi_{v}}\left(f_{2}\right) \quad v, w \in V \tag{1.10}
\end{equation*}
$$

Let $\left(J_{n}\right)_{n}$ be a sequence of compact open subgroups whose intersection is equal to the neutral element of $G$. The characteristic function $g_{n}$ of $J_{n} x_{m} \gamma J_{n}$ approaches the Dirac measure at $x_{m} \gamma$ as $n$ approaches $+\infty$. Thus, if $v, w \in V$, then $m_{\xi_{w}, \xi_{v}}\left(g_{n}\right)$ converges to $m_{\xi_{w}, \xi_{v}}\left(x_{m} \gamma\right)$. Then, by Corollary 2.11, the constant term $\tilde{J}\left(c_{v, w} \otimes g_{n}\right)$ converges to $c_{M} c_{S, x_{m}} \mathcal{W} \mathcal{M}\left(c_{v, w}\right)\left(x_{m} \gamma\right)$. We thus deduce the Theorem from (1.10).
